- Quality of service (QoS) ACLs: Used to classify and process data flows by priority.

ACLs are configured for a lot of reasons. Major reasons include:

- Network access control: To ensure network security, rules are defined to limit access of users to some services (for example, only access to the WWW and email services is permitted, and access to other services such as Telnet is prohibited), or to allow users to access services in a specified period of time, or to allow only specified hosts to access the network.
- QoS: QoS ACLs are used to preferentially classify and process important data flows. For details about the use of QoS ACLs, see the configuration manual related to QoS.

## 1.2 Applications

Application	Description
Access Control of an Enterprise Network	On an enterprise network, the network access rights of each department, for example, access rights of servers and use permissions of chatting tools (such as QQ and MSN), must be controlled according to requirements.

### 1.2.1 Access Control of an Enterprise Network

#### Scenario

Internet viruses can be found everywhere. Therefore, it is necessary to block ports that are often used by viruses to ensure security of an enterprise network as follows:

- Allow only internal PCs to access the server.
- Prohibit PCs of a non-financial department from accessing PCs of the financial department, and prohibit PCs of a non-R&D department from accessing PCs of the R&D department.

- Prohibit the staff of the R&D department from using chatting tools (such as QQ and MSN) during working hours from 09:00 to 18:00.

Figure 1- 1

<b>Remarks</b>	<p>Switch C at the access layer: It is connected to PCs of each department and to Switch B at the aggregation layer through the gigabit optical fiber (trunk mode).</p> <p>Switch B at the aggregation layer: Multiple virtual local area networks (VLANs) are divided. One VLAN is defined for one department. These VLANs are connected to Switch A at the core layer through the 10-gigabit optical fiber (trunk mode).</p> <p>Switch A at the core layer: It is connected to various servers, such as the File Transfer Protocol (FTP) server and Hypertext Transfer Protocol (HTTP) server, and to the Internet through firewalls.</p>
----------------	---

### Deployment

- Configure an extended ACL on the port G2/1 to filter data packets, thus protecting the network against the viruses. This port is located on a core-layer device (Switch A) and used to connect Switch A to the uplink port G2/1 of a router.
- Allow only internal PCs to access servers, and prohibit external PCs from accessing servers. Define and apply the extended IP ACLs on G2/2 or switch virtual interface (SVI) 2 that is used to connect Switch A to an aggregation layer device or server.
- Prohibit mutual access between specified departments. Define and apply the extended IP ACLs on G0/22 and G0/23 of Switch B.
- Configure and apply the time-based extended IP ACLs on SVI 2 of Switch B to prohibit the R&D department from using chatting tools (such as QQ and MSN) in a specified period of time.

## 1.3 Features

### Basic Concepts

## 📄 ACL

ACLs include basic ACLs and dynamic ACLs.

You can select basic or dynamic ACLs as required. Generally, basic ACLs can meet the security requirements. However, experienced hackers may use certain software to access the network by means of IP address spoofing. If dynamic ACLs are used, users are requested to pass identify authentication before accessing the network, which prevents hackers from intruding the network. Therefore, you can use dynamic ACLs in some sensitive areas to guarantee network security.

**i** IP address spoofing is an inherent problem of all ACLs, including dynamic ACLs. Hackers may use forged IP addresses to access the network during the validity period of authenticated user identities. Two methods are available to resolve this problem. One is to set the idle time of user access to a smaller value, which increases the difficulty in intruding networks. The other is to encrypt network data using the IPSec protocol, which ensures that all data is encrypted when arriving at a device.

ACLs are generally configured on the following network devices:

- Devices between the internal network and the external network (such as the Internet)
- Devices on the border of two network segments
- Devices connected to controlled ports

ACL statements must be executed in strict compliance with their sequence in the ACL. Comparison starts from the first statement. Once the header of a data packet matches a statement in the ACL, the subsequent statements are ignored and no longer checked.

## 📄 Input/Output ACLs, Filtering Field Template, and Rules

When receiving a packet on an interface, the device checks whether the packet matches any access control entry (ACE) in the input ACL of this interface. Before sending a packet through an interface, the device checks whether the packet matches any ACE in the output ACL of this interface.

When different filtering rules are defined, all or only some rules may be applied simultaneously. If a packet matches an ACE, this packet is processed according to the action policy (permit or deny) defined in this ACE. ACEs in an ACL identify Ethernet packets based on the following fields in the Ethernet packets:

Layer 2 (L2) fields:

- 48-bit source MAC address (containing all 48 bits)
- 48-bit destination MAC address (containing all 48 bits)
- 16-bit L2 type field

Layer 3 (L3) fields:

- Source IP address field (All source IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Destination IP address field (All destination IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Protocol type field

Layer 4 (L4) fields:

- Either a TCP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

- Either a UDP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

Filtering fields refer to the fields in packets that can be used to identify or classify packets when an ACE is generated. A filtering field template is a combination of these fields. For example, when an ACE is generated, packets are identified and classified based on the destination IP address field in each packet; when another ACE is generated, packets are identified and classified based on the source IP address field and UDP source port field in each packet. The two ACEs use different filtering field templates.

Rules refer to values of fields in the filtering field template of an ACE. For example, the content of an ACE is as follows:

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering field template is a combination of the following fields: source IP address field, IP protocol field, and TCP destination port field. The corresponding values (rules) are as follows: source IP address = Host 192.168.12.2; IP protocol = TCP; TCP destination port = Telnet.

Figure 1- 2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet

- i** A filtering field template can be a combination of L3 and L4 fields, or a combination of multiple L2 fields. The filtering field template of a standard or an extended ACL, however, cannot be a combination of L2 and L3 fields, a combination of L2 and L4 fields, or a combination of L2, L3, and L4 fields. To use a combination of L2, L3, and L4 fields, you can use the expert ACLs.
- i** An SVI associated with ACLs in the outgoing direction supports the IP standard, IP extended, MAC extended, and expert ACLs. If an MAC extended or expert ACL is configured to match the destination MAC address and is applied to the outgoing direction of the SVI, the related ACE can be configured but cannot take effect. If an IP extended or expert ACL is configured to match the destination IP address, but the destination IP address is not in the subnet IP address range of the associated SVI, the configured ACL cannot take effect. For example, assume that the address of VLAN 1 is **192.168.64.1 255.255.255.0**, an IP extended ACL is created, and the ACE is **deny udp any 192.168.65.10 0.0.255 eq 255**. If this ACL is applied to the outgoing interface of VLAN 1, the ACL cannot take effect because the destination IP address is not in the subnet IP address range of VLAN 1. If the ACE is **deny udp any 192.168.64.10 0.0.255 eq 255**, the ACL can take effect because the destination IP address is in the subnet IP address range of VLAN 1.

On a switch, if ACLs are applied to the outgoing direction of a physical port or an aggregate port (AP), the ACLs can filter only well-known packets (unicast or multicast packets), but not unknown unicast packets. That is, for unknown or broadcast packets, ACLs configured in the outgoing direction of a port does not take effect.

On a switch, if the input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared among all ports, the permit and default deny ACEs do not take effect, but other deny ACEs take effect.

On a switch, if the input ACL and QoS are shared, the permit ACEs do not take effect, other deny ACEs take effect, and the default deny ACE takes effect after the QoS ACE takes effect.

On a switch, you can run the **noFSOS-security compatible** command to make the permit and deny ACEs take effect at the same time when the port-based input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared.

If ACEs are added to an ACL and then the switch is restarted after an ACL is applied to the incoming direction of multiple SVIs, the ACL may fail to be configured on some SVIs due to the limited hardware capacity.

-  If an expert ACL is configured and applied to the outgoing direction of an interface, and some ACEs in this ACL contain the L3 matching information (e.g. the IP address and L4 port), non-IP packets sent to the device from this interface cannot be controlled by the permit and deny ACEs in this ACL.
-  If ACEs of an ACL (IP ACL or expert extended ACL) are configured to match non-L2 fields (such as SIP and DIP), the ACL does not take effect on tagged MPLS packets.

To allow users better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep 9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval respectively for the IPv4 ACL and the IPv6 ACL.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.
-  Only switches support the ACL logging function.

## 📄 ACL Packet Matching Counters

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL, which can be an IP ACL, MAC ACL, expert ACL, or IPv6 ACL. In addition, you can run the **clear counters access-list [acl-id | acl-name]** command to reset ACL counters for a new round of statistics.

-  Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.
-  Only switches support the ACL packet matching counters.

## Overview

Feature	Description
IP ACL	Control incoming or outgoing IPv4 packets of a device based on the L3 or L4 information in the IPv4 packet

Feature	Description
	header.
MAC Extended ACL	Control incoming or outgoing L2 packets of a device based on the L2 information in the Ethernet packet header.
Expert Extended ACL	Combine the IP ACL and MAC extended ACL into an expert extended ACL, which controls (permits or denies) incoming or outgoing packets of a device using the same rule based on the L2, L3, and L4 information in the packet header.
IPv6 ACL	Control incoming or outgoing IPv6 packets of a device based on the L3 or L4 information in the IPv6 packet header.
ACL80	Customize the matching fields and mask for scenarios where fixed matching fields cannot meet the requirements.
ACL Redirection	Redirect incoming packets of a device that match ACEs to a specified outgoing interface.
Global Security ACL	Make an ACL take effect in the incoming direction of all interfaces, instead of applying the ACL on every interface.
Security Channel	Allow packets to bypass the check of access control applications, such as DOT1X and Web authentication, to meet requirements of some special scenarios.
SVI Router ACL	Enable users in the same VLAN to communicate with each other.
ACL Logging	Output ACL packet matching logs at a specified interval according to requirements. The logs help users learn the packet matching result of a specified ACE.

### 1.3.1 IP ACL

The IP ACL implements refined control on incoming and outgoing IPv4 packets of a device. You can permit or deny the entry of specific IPv4 packets to a network according to actual requirements to control access of IP users to network resources.

#### Working Principle

Define a series of IP access rules in the IP ACL, and then apply the IP ACL either in the incoming or outgoing direction of an interface or globally. The device checks whether the incoming or outgoing IPv4 packets match the rules and accordingly forwards or blocks these packets.

To configure an IP ACL, you must specify a unique name or ID for the ACL of a protocol so that the protocol can uniquely identify each ACL. The following table lists the protocols that can use IDs to identify ACLs and the range of IDs.

Protocol	ID Range
Standard IP	1–99, 1300–1999
Extended IP	100–199, 2000–2699

Basic ACLs include the standard IP ACLs and extended IP ACLs. Typical rules defined in an ACL contain the following matching fields:

- Source IP address
- Destination IP address
- IP protocol number
- L4 source port ID or ICMP type
- L4 destination port ID or ICMP code

The standard IP ACL (ID range: 1–99, 1300–1999) is used to forward or block packets based on the source IP address, whereas the extended IP ACL (ID range: 100–199, 2000–2699) is used to forward or block packets based on a combination of the preceding matching fields.

For an individual ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

For routing products, the ICMP code matching field in an ACL rule is ineffective for ICMP packets whose ICMP type is 3. If the ICMP code of ICMP packets to be matched is configured in an ACL rule, the ACL matching result of incoming ICMP packets of a device whose ICMP type is 3 may be different from the expected result.

### ⚡ Implicit "Deny All Traffic" Rule Statement

At the end of every IP ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 1 permit host 192.168.4.12
```

This ACL permits only packets sent from the source host 192.168.4.12, and denies packets sent from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 1 deny any**.

If the ACL contains only the following statement:

```
access-list 1 deny host 192.168.4.12
```

Packets sent from any host will be denied when passing through this port.

- ! When defining an ACL, you must consider the routing update packets. As the implicit "deny all traffic" statement exists at the end of an ACL, all routing update packets may be blocked.

### ⚡ Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and denies all traffic, all subsequent statements will not be checked.

For example:

```
access-list 101 deny ip any any
access-list 101 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

The first rule statement denies all IP packets. Therefore, Telnet packets from the host on the network 192.168.12.0/24 will be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

## Related Configuration

### ⚡ Configuring an IP ACL

By default, no IP ACL is configured on a device.

Run the **ip access-list {standard|extended} {acl-name|acl-id}** command in global configuration mode to create a standard or an extended IP ACL and enter standard or extended IP ACL mode.

## ▾ Adding ACEs to an IP ACL

By default, a newly created IP ACL contains an implicit ACE that denies all IPv4 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv4 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv4 packets, add some ACEs to the ACL.

For a standard IP ACL, add ACEs as follows:

- No matter whether the standard IP ACL is a named or number ACL, you can run the following command in standard IP ACL mode to add an ACE:

```
[ sn ] { permit | deny } { host source | any | source source-wildcard } [ time-range time-range-name ] [ log ]
```

- For a numbered standard IP ACL, you can also run the following command in global configuration mode to add an ACE: **access-list acl-id { permit | deny } { host source | any | source source-wildcard } [ time-range tm-rng-name ] [ log ]**

For an extended IP ACL, you can add ACEs as follows:

- No matter whether the extended IP ACL is a named or numbered ACL, you can run the following command in extended IP ACL mode to add an ACE:

```
[ sn ] { permit | deny } protocol { host source | any | source source-wildcard } { host destination | any | destination destination-wildcard } [ [ precedence precedence ] [ tos tos ] ] [ [ dscp dscp ] [ ecn ecn ] ] [ udf udf-id header pos value mask ] [ fragment ] [ fragment-ipid fragment-ipid ] [ time-range time-range-name ] [ log ]
```

- For a numbered extended IP ACL, you can also run the following command in global configuration mode to add an ACE: **access-list acl-id { permit | deny } protocol { host source | any | source source-wildcard } { host destination | any | destination destination-wildcard } [ [ precedence precedence ] [ tos tos ] ] [ [ dscp dscp ] [ ecn ecn ] ] [ fragment ] [ fragment-ipid fragment-ipid ] [ time-range time-range-name ] [ log ]**

## ▾ Applying an IP ACL

By default, the IP ACL is not applied to any interface, that is, the IP ACL does not filter incoming or outgoing IP packets of the device.

Run the **ip access-group { acl-id | acl-name } { in | out } [ reflect | counter-only | forward-plane | priority ]** command in interface configuration mode to apply a standard or an extended IP ACL to a specified interface.

To collect statistics on packets with some features, run the **ip access-group { acl-id | acl-name } { in | out } counter-only** command on the interface. The count rule takes effect only to **permit** rules and does not take effect to **deny** rules in the ACL.

After an ACL is used as a counter-only ACL, the counter function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on interfaces as a common application ACL. That is, ACLs with the same ID or name cannot be used as a counter-only ACL and a common application ACL at the same time.

Configure **forward-plane** so that ACL is only applied to the forwarding plane.

Configure **priority** to set the priority of ACL applied to the SVI interface, so that this ACL can have the highest priority on the forwarding plane of SVI interface.

### 1.3.2 MAC Extended ACL

The MAC extended ACL implements refined control on incoming and outgoing packets based on the L2 header of packets. You can permit or deny the entry of specific L2 packets to a network, thus protecting network resources against attacks or control users' access to network resources.

#### Working Principle

Define a series of MAC access rules in the MAC extended ACL, and then apply the ACL to the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an MAC extended ACL, you must specify a unique name or ID for this ACL to uniquely identify the ACL. The following table lists the range of IDs that identify MAC extended ACLs.

Protocol	ID Range
MAC extended ACL	700–799

Typical rules defined in an MAC extended ACL include:

- Source MAC address
- Destination MAC address
- Ethernet protocol type

The MAC extended ACL (ID range: 700–799) is used to filter packets based on the source or destination MAC address and the Ethernet type in the packets.

For an individual MAC extended ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

If ACEs in an MAC extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the MAC extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

#### ⚡ Implicit "Deny All Traffic" Rule Statement

At the end of every MAC extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only packets from the host with the MAC address 00d0.f800.0001, and denies packets from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 700 deny any any**.

#### Related Configuration

##### ⚡ Configuring an MAC Extended ACL

By default, no MAC extended ACL is configured on a device.

Run the **mac access-list extended {acl-name | acl-id}** command in global configuration mode to create an MAC extended ACL and enter MAC extended ACL mode.

##### ⚡ Adding ACEs to an MAC Extended ACL

By default, a newly created MAC extended ACL contains an implicit ACE that denies all L2 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an MAC extended ACL as follows:

- No matter whether the MAC extended ACL is a named or numbered ACL, you can run the following command in MAC extended ACL mode to add an ACE:

```
[sn] { permit | deny } { any | host src-mac-addr | src-mac-addrmask } { any | host dst-mac-addr | dst-mac-addrmask } [ethernet-type] [coscos] [innercos] [ time-range tm-rng-name ]
```

- For a numbered MAC extended ACL, you can also run the following command in global configuration mode to add an ACE:  
**access-list** *acl-id* { permit | deny } { any | host *src-mac-addr* | *src-mac-addrmask* } { any | host *dst-mac-addr* | *dst-mac-addrmask* } [ethernet-type] [coscos] [innercos] [ time-range *time-range-name* ]

### 📄 Applying an MAC Extended ACL

By default, the MAC extended ACL is not applied to any interface, that is, the created MAC extended ACL does not filter incoming or outgoing L2 packets of a device.

Run the **mac access-group** { *acl-id* | *acl-name* } { in | out } [ counter-only | forward-plane | priority ] command in interface configuration mode to apply an MAC extended ACL to a specified interface.

To collect statistics on packets with some features, run the **mac access-group** { *acl-id* | *acl-name* } { in | out } counter-only command on the interface. The count rule takes effect only to **permit** rules and does not take effect to **deny** rules in the ACL.

After an ACL is used as a counter-only ACL, the counter function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on interfaces as a common application ACL. That is, ACLs with the same ID or name cannot be used as a counter-only ACL and a common application ACL at the same time.

Configure **forward-plane** so that ACL is only applied to the forwarding plane.

Configure **priority** to set the priority of ACL applied to the SVI interface, so that this ACL can have the highest priority on the forwarding plane of SVI interface.

### 1.3.3 Expert Extended ACL

You can create an expert extended ACL to match the L2 and L3 information in packets using the same rule. The expert extended ACL can be treated as a combination and enhancement of the IP ACL and the MAC extended ACL because the expert extended ACL can contain ACEs in both the IP ACL and the MAC extended ACL. In addition, the VLAN ID can be specified in the expert extended ACL to filter packets.

#### Working Principle

Define a series of access rules in the expert extended ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an expert extended ACL, you must specify a unique name or ID for this ACL so that the protocol can uniquely identify each ACL. The following table lists the ID range of the expert extended ACL.

Protocol	ID Range
Expert extended ACL	2700–2899

When an expert extended ACL is created, defined rules can be applied to all packets. The device determines whether to forward or block packets by checking whether packets match these rules.

Typical rules defined in an expert extended ACL include:

- All information in the basic ACL and MAC extended ACL
- VLAN ID

The expert extended ACL (ID range: 2700–2899) is a combination of the basic ACL and MAC extended ACL, and can filter packets based on the VLAN ID.

For an individual expert extended ACL, multiple independent statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL.

If rules in an expert extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the expert extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

The Virtual Extensible LAN (VXLAN) field in the expert extended ACL of a data center product is mainly used to match the inner packets in the VXLAN. Therefore, you can use the expert extended ACL in VXLAN mode to match the inner IP address of the VXLAN.

The VXLAN field in the N18K-CMX expert extended ACL of a data center product cannot match the 5-tuple of the inner and external layer concurrently. However, FS N5860 only needs to match the tunnel start packets and tunnel termination packets. Therefore, with N5860, you can only use a common 5-tuple field to match the original packets without applying the VXLAN field in the expert extended ACL.

When a device needs to match VXLAN packets, you can specify the destination port ID of the VXLAN protocol to confirm VXLAN packets. You can also specify whether matched VXLAN packets carry tags.

The UDF field in the expert extended ACL of a data center product is a customized field. Users should customize the protocol layer, offset, data and mask.

MPLS in the expert extended ACL of a data center product can provide the matching rules for the IP field in MPLS packets.

### ↘ Implicit "Deny All Traffic" Rule Statement

At the end of every expert extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 2700 permit 0x0806 any any any any any
```

This ACL permits only ARP packets whose Ethernet type is 0x0806, and denies all other types of packets. This is because the following statement exists at the end of this ACL: **access-list 2700 deny any any any any any**.

## Related Configuration

### ↘ Configuring an Expert Extended ACL

By default, no expert extended ACL is configured on a device.

Run the **expert access-list extended {acl-name | acl-id}** command in global configuration mode to create an expert extended ACL and enter expert extended ACL mode.

### ↘ Adding ACEs to an Expert Extended ACL

By default, a newly created expert extended ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an expert extended ACL as follows:

- No matter whether the expert extended ACL is a named or numbered ACL, you can run the following command in expert extended ACL mode to add an ACE:

```
[sn]{ permit | deny } [protocol] [ethernet-type] [ cos[out] [inner in]] [[VID [out][inner in]]] {source source-wildcard | host source | any}{host source-mac-address|any}{destination destination-wildcard | host destination | any}{host destination-mac-address | any} [[precedence precedence][tos tos] | [dscp dscp] [ecn ecn] ] [fragment] [ fragment-ipid fragment-ipid ] [range lowerupper] [[udf udf-id header pos value mask ] | [ int-flag ]] [time-range time-range-name]]
```

- When VXLAN packets need to match the inner 5-tuple, you can use the following command in expert ACL:

```
[sn]{ permit | deny } vxlan protocol {source source-wildcard | host source | any} {destination destination-wildcard | host destination | any} [tagged] [udp-dport dport][time-rangetime-range-name]]
```

This command is used to configure an ACE in the ACL. When *protocol* is set to **TCP** or **UDP**, you can configure a Layer-4 port ID to indicate the VXLAN inner port ID to be matched.

- For a numbered expert extended ACL, you can also run the following command in expert extended ACL mode to add an ACE:

```
access-list acl-id { permit | deny } [protocol] [ethernet-type] [ cos[out] [inner in]] [[VID [out][inner in]]] {source source-wildcard | host source | any}{host source-mac-address|any}{destination destination-wildcard | host destination | any}{host destination-mac-address | any} [[precedence precedence][tos tos] | [dscp dscp] [ecn ecn] ] [fragment] [ fragment-ipid fragment-ipid ] [range lowerupper] [[udf udf-id header pos value mask ] | [ int-flag ]] [time-range time-range-name]]
```

### 📌 Applying an Expert Extended ACL

By default, the expert extended ACL is not applied to any interface, that is, the created expert extended ACL does not filter incoming or outgoing L2 or L3 packets of a device.

Run the **expert access-group** {acl-id | acl-name} { in | out} [ counter-only | forward-plane | priority ] command in interface configuration mode to apply an expert extended ACL to a specified interface.

To collect statistics on packets with some features, run the **expert access-group** {acl-id | acl-name} {in|out} counter-only command on the interface. The count rule takes effect only to **permit** rules and does not take effect to **deny** rules in the ACL.

After an ACL is used as a counter-only ACL, the counter function cannot be globally enabled for the ACL, and the ACL cannot be applied globally or on interfaces as a common application ACL. That is, ACLs with the same ID or name cannot be used as a counter-only ACL and a common application ACL at the same time.

Configure **forward-plane** so that ACL is only applied to the forwarding plane.

Configure **priority** to set the priority of ACL applied to the SVI interface, so that this ACL can have the highest priority on the forwarding plane of SVI interface.

### 1.3.4 IPv6 ACL

The IPv6 ACL implements refined control on incoming and outgoing IPv6 packets of a device. You can permit or deny the entry of specific IPv6 packets to a network according to actual requirements to control access of IPv6 users to network resources.

#### Working Principle

Define a series of IPv6 access rules in the IPv6 ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing IPv6 packets match the rules and accordingly forwards or blocks these packets.

To configure an IPv6 ACL, you must specify a unique name for this ACL.

- 📘 Unlike the IPACL, MAC extended ACL, and expert extended ACL, you can specify only a name but not an ID for the IPv6 ACL created.

- i** Only one IP ACL, or one MAC extended ACL, or one expert extended ACL can be applied to the incoming or outgoing direction of an interface. Besides, one more IPv6 ACL can be applied.

### ⌵ Implicit "Deny All Traffic" Rule Statement

At the end of every IPv6 ACL is an implicit "deny all IPv6 traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
ipv6 access-list ipv6_acl
 10 permit ipv6 host 200::1 any
```

This ACL permits only IPv6 packets from the source host 200::1, and denies IPv6 packets from all other hosts. This is because the following statement exists at the end of this ACL: deny ipv6 any any.

- !** Although the IPv6 ACL contains the implicit "deny all IPv6 traffic" rule statement by default, it does not filter ND packets.

### ⌵ Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and permits all IPv6 traffic, all subsequent statements will not be checked.

For example:

```
ipv6 access-list ipv6_acl
 10 permit ipv6 any any
 20 deny ipv6 host 200::1 any
```

As the first rule statement permits all IPv6 packets, all IPv6 packets sent from the host 200::1 does not match the subsequent deny rule with the serial number of 20, and therefore will not be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

## Related Configuration

### ⌵ Configuring an IPv6 ACL

By default, no IPv6 ACL is configured on a device.

Run the **ipv6 access-list *acl-name*** command in global configuration mode to create an IPv6 ACL and enter IPv6 ACL mode.

### ⌵ Adding ACEs to an IPv6 ACL

By default, a newly created IPv6 ACL contains an implicit ACE that denies all IPv6 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv6 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv6 packets, add some ACEs to the ACL.

Run the following command in IPv6 ACL mode to add an ACE:

```
[sn] {permit | deny } protocol {src-ipv6-prefix/prefix-len | host src-ipv6-addr } any {dst-ipv6-pfx/pfx-len | host dst-ipv6-addr } any } [range lower upper] [dscp dscp] [flow-label/flow-label] [fragment] [ udf udf-id header pos value mask ] [time-range tm-rng-name] [ log ]
```

## 📌 Applying an IPv6 ACL

By default, the IPv6 ACL is not applied to any interface, that is, the IPv6 ACL does not filter incoming or outgoing IPv6 packets of a device.

Run the `ipv6 traffic-filter acl-name {in|out} [counter-only | priority]` command in interface configuration mode to apply an IPv6 ACL to a specified interface.

Configure `priority` to set the priority of ACL applied to the SVI interface, so that this ACL can have the highest priority on the forwarding plane of SVI interface.

### 1.3.5 ACL80

ACL80 refers to the expert advanced ACL, and is also called custom ACL. It filters packets based on the first 80 bytes of every packet. Among these 80 bytes, the SMAC, DMAC, SIP, DIP, and ETYPE fields in a packet are mandatory, and you can specify the remaining 16 bytes.

#### Working Principle

A packet consists of a number of bytes. ACL80 allows you to match the specified 16 bytes by bit in the first 80 bytes of a packet. Any bit of a 16-byte field can be set to a value (0 or 1), indicating whether the bit is compared. When any byte is filtered, three factors are considered: content of the matching field, mask of the matching field, and the start position for matching. Bits of the matching field content are in one-to-one mapping relationship with bits of the matching field mask. The filtering rule specifies the value of the field to be filtered. The filtering field template specifies whether the corresponding field in the filtering rule should be filtered. (1 indicates that the bit specified in the filtering rule should be matched; 0 indicates that the bit specified in the filtering rule is not matched.)

Therefore, when it is required to match a specific bit, you must set the corresponding bit to 1 in the filtering field template. For example, if the bit is set to 0 in the filtering field template, no bit is matched no matter which bit is specified in the filtering rule.

For example,

```
FS(config)#expert access-list advanced name
FS(config-exp-dacl)#permit 00d0f8123456 ffffffff 0
FS(config-exp-dacl)#deny 00d0f8654321 ffffffff 6
```

The custom ACL matches any byte of the first 80 bytes in a L2 data frame according to user' definition, and filters packets accordingly. To properly use a custom ACL, you must have an in-depth understanding about the structure of a L2 data frame. The following shows the first 64 bytes of a L3 data frame (every letter represents a hexadecimal number, and every two letters represent one byte):

```
AAAA AAAA AAAA BBBB BBBB BBBB BBBB CCCC DDDD
DDDD EE FF GG HH HH HH IIII JJ KK LL LL MM MM
NNNN OO PP QQ QQ RRRR RRRR RRRR RRRR SS SS SS TT TT
UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb
```

The following table describes the meaning and offset of each letter:

Letter	Meaning	Offset	Letter	Meaning	Offset
A	Destination MAC address	0	O	Time To Live (TTL) field	34
B	Source MAC address	6	P	Protocol number	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length	16	R	Source IP address	38

Letter	Meaning	Offset	Letter	Meaning	Offset
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Cntl field	20	U	TCP destination port	48
H	OFS Code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version number	26	XY	IP header length and reserved bit	58
K	TOS field	27	Z	Reserved bit and flags bit	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Miscellaneous	62
N	Flags field	32			

In the above table, the offset of each field is the offset of this field in the tagged 802.3 SNAP packet. In a custom ACL, you can use the rule mask and offset jointly to extract any byte from the first 80 bytes of a data frame, compare the byte with the rule customized in the ACL, and then filter matched data frames for further processing. Customized rules may be some fixed attributes of data. For example, to obtain all TCP packets, you can define the rule as "06", rule mask as "FF", and offset as "35". Then, the device can use the rule mask and offset jointly to extract the content of TCP protocol number field in a received data frame, and compare the extracted content with the rule to obtain all TCP packets.

-  Only switches support the ACL80.
-  The ACL80 supports filtering of the Ethernet, 803.3 SNAP, and 802.3 LLC packets. If the values of the fields from DSAP to cntl are set to AAAA03, the ACL is used to filter the 803.3 SNAP packets. If the values of the fields from DSAP to cntl are set to E0E003, the ACL is used to filter the 803.3 LLC packets. The value of the cntl field cannot be configured to filter Ethernet packets.
-  The ACL80 can be configured to compare packets with any of the 16 bytes. If the 16 bytes are already used, no ACE can be configured to compare packets with fields in any other bytes.

## Related Configuration

### 📄 Configuring an Expert Advanced ACL

By default, no expert advanced ACL is configured on a device.

Run the **expert access-list advanced *acl-name*** command in global configuration mode to create an expert advanced ACL and enter expert advanced ACL mode.

### 📄 Adding ACEs to an Expert Advanced ACL

By default, a newly created expert advanced ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

- Run the **[sn]{permit|deny} hex hex-mask offset** command in expert advanced ACL mode to add an ACE to the expert advanced ACL.

### 📄 Applying an Expert Advanced ACL

By default, the expert advanced ACL is not applied to any interface, that is, the created expert advanced ACL does not filter incoming or outgoing packets of a device.

Run the **expert access-group *acl-name* {in|out} [forward-plane|priority]** command in interface configuration mode to apply an expert advanced ACL to a specified interface.

Configure **forward-plane** so that ACL is only applied to the forwarding plane.

Configure **priority** to set the priority of ACL applied to the SVI interface, so that this ACL can have the highest priority on the forwarding plane of SVI interface.

### 1.3.6 ACL Redirection

ACL redirection allows a device to analyze received packets and redirect the packets to a specified port for forwarding. To analyze specific incoming packets of a device, you can configure the ACL redirection function to redirect packets meeting rules to a specified port and capture packets on this port for analysis.

#### Working Principle

Bind different ACL policy to an interface and specify an output destination interface for each policy. When receiving packets on this interface, the device searches ACL policies bound to this interface one by one. If packets match criteria described in a certain policy, the device forwards packets on the destination interface specified by the policy, thus redirecting packets based on traffic.

-  Only switches support the ACL redirection function.
-  ACL redirection takes effect only in the incoming direction of an interface.

#### Related Configuration

##### ▾ Configuring an ACL

Before configuring ACL redirection, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

##### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ▾ Configuring ACL Redirection

By default, ACL redirection is not configured on a device.

Run the **redirect destination interface *interface-name* acl {*acl-id* | *acl-name*}** in command in interface configuration mode to configure ACL redirection.

-  You can configure the ACL redirection function only on an Ethernet interface or AP.

### 1.3.7 Global Security ACL

To meet the requirements of security deployment, the port-based ACL is often configured to filter out virus packets and obtain packets with certain characteristics, for example, packets that attack the TCP port. Various virus packets exist in a global network environment, and the identification features of virus packets under each port are identical or similar. Therefore, an ACL is generally created. After the deny ACE for matching virus signatures is added to the ACL, the port-based ACL is applied to each port on the switch to filter out virus packets.

For two reasons, it is not convenient to use the port-based ACLs in antivirus scenarios such as virus filtering. The first reason is that the port-based ACL must be configured on every port, which results in repeated configuration, poor operation performance, and

over-consumption of ACL resources. The second reason is that the access control function of the ACL is weakened. As the port-based ACL is used for virus filtering, basic functions of the ACL, such as route update restriction and network access restriction, cannot be used properly. The global security ACL can be used for global antivirus deployment and defense without affecting the port-based ACL. By running only one command, you can make the global security ACL take effect on all L2 interfaces. In contrast, the port-based ACL must be configured on every interface.

### Working Principle

The global security ACL takes effect on all L2 interfaces. When both the global security ACL and the port-based ACL are configured, both take effect. Packets that match the global security ACL are directly filtered out as virus packets. Packets that do not match the global security ACL are still controlled by the port-based ACL. You can disable the global security ACL on some ports so that these ports are not controlled by the global security ACL.

-  The global security ACL is mainly used for virus filtering. Therefore, in an ACL associated with the global security ACL, only the deny ACEs take effect, and the permit ACEs do not take effect.
-  Unlike the secure ACL applied to a port, the global security ACL does not contain the default "deny all traffic" ACE, that is, all packets that do not match the ACL are permitted.
-  A global secure ACL can take effect either on a L2 port or a routed port. That is, it takes effect on all the following types of ports: access port, trunk port, hybrid port, routed port, and AP (L2 or L3). The global secure ACL does not take effect on an SVI.
-  You can disable the global security ACL on an individual physical port or AP, but not on a member port of an AP.
-  The global secure ACL supports only the associated IP standard ACL, IP extended ACL, MAC extended ACL and expert extended ACL.

### Related Configuration

#### ▾ Configuring an ACL

Before configuring the global security ACL, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

#### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL.

#### ▾ Configuring a Global Security ACL

By default, no global security ACL is configured on a device.

Run the `{ip|mac|Expert}access-group acl-id {in|out}` command in global configuration mode to enable the global security ACL.

Run the `ipv6 traffic-filter acl-name {in|out}` command to enable the global IPv6 security ACL.

#### ▾ Configuring an Exclusive Interface of the Global Security ACL

By default, no exclusive interface is configured for the global security ACL on a device.

Run the `no global ip access-group` command in interface configuration to disable the global security ACL on a specified interface.

### 1.3.8 Security Channel

In some application scenarios, packets meeting some characteristics may need to bypass the checks of access control applications. For example, before DOT1X authentication, users are allowed to log in to a specified website to download the DOT1X authentication client. The security channel can be used for this purpose. When the security channel configuration command is executed to apply a secure ACL globally or to an interface, this ACL becomes a security channel.

#### Working Principle

The security channel is also an ACL, and can be configured globally or for a specified interface. When arriving at an interface, packets are checked on the security channel. If meeting the matching conditions of the security channel, packets directly enter a switch without undergoing the access control, such as port security, Web authentication, 802.1x, and IP+MAC binding check. A globally applied security channel takes effect on all interfaces except exclusive interfaces.

-  The deny ACEs in an ACL that is applied to a security channel do not take effect. In addition, this ACL does not contain an implicit "deny all traffic" rule statement at the end of the ACL. If packets do not meet matching conditions of the security channel, they are checked according to the access control rules in compliance with the relevant process.
-  You can configure up to eight exclusive interfaces for the global security channel. In addition, you cannot configure interface-based security channel on these exclusive interfaces.
-  If a security channel is applied to an interface while a global security channel exists, this global security channel does not take effect on this interface.
-  If both port-based migratable authentication mode and security channel are applied to an interface, the security channel does not take effect.
-  An IPv6 ACL cannot be configured as a security channel.
-  Only switches support the security channel.

#### Related Configuration

##### ▾ Configuring an ACL

Before configuring the security channel, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

##### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, or expert extended ACL.

##### ▾ Configuring a Security Channel on an Interface

By default, no security channel is configured on an interface of a device.

Run the **security access-group** {*acl-id* | *acl-name*} command in interface configuration mode to configure the security channel on an interface.

##### ▾ Configuring a Global Security Channel

By default, no global security channel is configured on a device.

Run the **security global access-group** {*acl-id* | *acl-name*} command in interface configuration mode to configure a global security channel.

## ▾ **Configuring an Exclusive Interface for the Global Security Channel**

By default, no exclusive interface is configured for the global security channel on a device.

Run the **securityuplinkenable** command in interface configuration mode to configure a specified interface as the exclusive interface of the global security channel.

### **1.3.9 SVI Router ACL**

By default, an ACL that is applied to an SVI also takes effect on L2 packets forwarded within a VLAN and L3 packets forwarded between VLANs. Consequently, users in the same VLAN may fail to communicate with each other. Therefore, a switchover method is provided so that the ACL that is applied to an SVI takes effect only on routing packets between VLANs.

#### **Working Principle**

By default, the SVI router ACL function is disabled, and an SVI ACL takes effect on L3 packets forwarded between VLANs and L2 packets forwarded within a VLAN. After the SVI router ACL function is enabled, the SVI ACL takes effect only on L3 packets forwarded between VLANs.

Only switches support the SVI router ACL.

#### **Related Configuration**

## ▾ **Configuring an ACL**

Before configuring the SVI router ACL, configure and apply an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

## ▾ **Adding ACEs to an ACL**

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

## ▾ **Applying an ACL**

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL. Apply the ACL in SVI configuration mode.

## ▾ **Configuring the SVI Router ACL**

Run the **svi router-acls enable** command in global configuration mode to enable the SVI router ACL so that the ACL that is applied to an SVI takes effect only on packets forwarded at L3, and not on packets forwarded at L2 within a VLAN.

### **1.3.10 ACL Logging**

ACL logging is used to monitor the running status of ACEs in an ACL and provide essential information for routine network maintenance and optimization.

#### **Working Principle**

To better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep 9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs; otherwise, logs are not output.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.

Only switches support the ACL logging function.

You can configure the ACL logging option only for an IP ACL or an IPv6 ACL.

### Related Configuration

#### ↘ Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

#### ↘ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

#### ↘ Configuring the Log Update Interval

Run the `{ip | ipv6} access-list log-update interval time` command in the configuration mode to configure the interval at which the ACL logs are output.

#### ↘ Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL.

### 1.3.11 Packet Matching Counters

In addition to ACL logs, packet matching counters provide another choice for routine network maintenance and optimization.

#### Working Principle

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL. When a packet matches the ACE, the corresponding counter increments by 1. You can run the `clear counters access-list [ acl-id | acl-name ]` command to reset counters of all ACEs in an ACL for a new round of statistics.

-  Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.

You can enable packet matching counters on an IP ACL, MAC ACL, expert ACL, or IPv6 ACL.

Only switches support the ACL packet matching counters.

## Related Configuration

### ✚ Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

### ✚ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the ACL. Note that the ACL logging option must be configured.

### ✚ Enabling Packet Matching Counters

To enable packet matching counters on an IP ACL, MAC ACL, or expert ACL, run the **{mac | expert | ip} access-list counter {acl-id | acl-name}** command in global configuration mode.

To enable packet matching counters on an IPv6 ACL, run the **ipv6 access-list counter acl-name** command in global configuration mode.

### ✚ Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

### ✚ Clearing Packet Matching Counters

Run the **clear counters access-list [acl-id | acl-name]** command in privileged EXEC mode to reset packet matching counters.

## 1.3.12 Fragmented Packet Matching Mode

In fragmented packet matching mode, an ACL can implement more refined control on fragmented packets.

### Working Principle

IP packets may be fragmented when transmitted on the network. When fragmentation occurs, only the first fragment of the packet contains the L4 information, such as the TCP/UDP port number, ICMP type, and ICMP code, and other fragmented packets do not contain the L4 information. By default, if an ACE contains the fragment flag, fragmented packets except the first fragments are filtered. If an ACE does not contain the fragment flag, all fragmented packets (including the first fragments) are filtered. In addition to this default fragmented packet matching mode, a new fragmented packet matching mode is provided. You can switch between the two fragmented packet matching modes as required on a specified ACL. In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and packets are fragmented, the first fragments are compared with all the matching fields (including L3 and L4 information) defined in the ACE, and other fragmented packets are compared with only the non-L4 information defined in the ACE.

 In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and the action is Permit, this type of ACE occupies more hardware entries. In an extreme case, this will reduce by half the number of hardware entries. If Established is configured for filter the TCP flag in an ACE, more hardware entries will be occupied.

 The ACL will be temporarily ineffective during switchover of the fragmented packet matching mode.

In the new fragmented packet matching mode, if an ACE does not contain the fragment flag, the L4 information of packets needs to be compared, and the action is Permit, the ACE checks the L3 and L4 information of the first fragments of packets, and checks

only the L3 information of other fragmented packets. If the action is Deny, the ACE checks only the first fragments of packets, and ignores other fragmented packets.

In the new fragmented packet matching mode, if an ACE contains the fragment flag, the ACE checks only fragmented packets but not the first fragments of packets no matter whether the action in the ACE is Permit or Deny.

Only the IP extended ACL and the expert extended ACL support switching between the two fragmented packet matching modes.

Only switches support filtering of fragmented packets.

## Related Configuration

### ▾ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and expert extended ACL. Note that the fragment option must be added.

### ▾ Switching the Fragmented Packet Matching Mode

Run the `[no]{ip|expert}access-list new-fragment-mode {acl-id|acl-name}` command in global configuration mode to switch the fragmented packet matching mode.

### ▾ Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

## 1.4 Limitations

On the N5860/N8560/NC8200 series products, the ACL applied to the inbound direction does not support "NEQ" matching on layer-4 ports for TCP and UDP packets, and the ACL applied to the outbound direction supports only "EQ" matching on layer-4 ports for TCP and UDP packets.

IPv6 ACLs configured on the N5860/N8560/NC8200 series products support matching by the following fields: **protocol**, **sip**, **I4\_src**, **dip**, **I4\_dst**, **dscp**, and **flow\_label**. An IPv6 ACL supports matching only based on the following two field groups:

- protocol, sip, I4\_src, I4\_dst, dscp, flow\_label, range
- protocol, dip, I4\_src, I4\_dst, dscp, flow\_label, range
- An ACL cannot use all the fields for matching. In addition, IPv6 ACLs do not support matching by fragment nor matching by flow label in the outbound direction.
- When only high-order 64 bits (the mask length is less than or equal to 64) need to be matched for the source IP address and destination IP address, matching by the IPv6 5-tuple is supported.

On the N5860/N8560/NC8200 series products, security ACLs applied to an SVI are effective to both intra-VLAN packets forwarded by bridges and inter-VLAN routing packets. As a result, users in the VLAN cannot perform communication.

The N5860/N8560/NC8200 series products cannot identify the fragment flag field in IPv6 packets. If an IPv6 ACL contains the fragment flag, the fragment flag is ignored during packet matching. This is equivalent to absence of the fragment flag in ACLs, and matching is performed on all packets, including the first-fragment packets and non-first-fragment packets.

The N5860/N8560/NC8200 series products support the switching of the fragment packet matching mode when IP extended ACLs or expert extended ACLs are applied.

On the N5860/N8560/NC8200 series products, ACL 80 supports only the following common fields: destination MAC address, source MAC address, VID, ETYPE, IP protocol number, source IPv4 address, destination IPv4 address, destination port ID, source port ID, ICMP type, and ICMP code.

## 1.5 Configuration

Configuration Item	Description and Command	
Configuring an IP ACL	 (Optional) It is used to filter IPv4 packets.	
	<b>ip access-list standard</b>	Configures a standard IP ACL.
	<b>ip access-list extended</b>	Configures an extended IP ACL.
	<b>permit host any time-range log</b>	Adds a permit ACE to a standard IP ACL.
	<b>deny host any time-range log</b>	Adds a deny ACE to a standard IP ACL.
	<b>permit host any host any tos dscp precedence fragment fragment-ipid <i>fragment-ipid</i> time-range log</b>	Adds a permit ACE to an extended IP ACL.
	<b>deny host any host any tos dscp precedence fragment fragment-ipid <i>fragment-ipid</i> time-range log</b>	Adds a deny ACE to an extended IP ACL.
	<b>ip access-group in out</b>	Applies a standard or an extended IP ACL.
Configuring an MAC Extended ACL	 (Optional) It is used to filter L2 packets.	
	<b>mac access-list extended</b>	Configures a MAC extended ACL.
	<b>permit any host any host cos inner time-range</b>	Adds a permit ACE to a MAC extended ACL.
	<b>deny any host any host cos inner time-range</b>	Adds a deny ACE to a MAC extended ACL.
	<b>mac access-group in out</b>	Applies a MAC extended ACL.
Configuring an Expert Extended ACL	 (Optional) It is used to filter L2 and L3 packets.	
	<b>expert access-list extended</b>	Configures an expert extended ACL.
	<b>permit cos inner VID inner host any host any host any precedence tos fragment fragment-ipid range time-range</b>	Adds a permit ACE to an expert extended ACL.
	<b>deny cos inner VID inner host any host any host any precedence tos fragment fragment-ipid range time-range</b>	Adds a deny ACE to an expert extended ACL.
	<b>expert access-group in out</b>	Applies an expert extended ACL.

Configuration Item	Description and Command	
Configuring an IPv6 Extended ACL	 (Optional) It is used to filter IPv6 packets.	
	<b>ipv6 access-list</b>	Configures an IPv6 ACL.
	<b>permit host any host any range dscp flow-label fragment time-range log</b>	Adds a permit ACE to an IPv6 ACL.
	<b>deny host any host any range dscp flow-label fragment time-range log</b>	Adds a deny ACE to an IPv6 ACL.
	<b>ipv6 traffic-filter in out</b>	Applies an IPv6 ACL.
Configuring an ACL80	 (Optional) It is used to customize the fields for filter L2 and L3 packets.	
	<b>expert access-list advanced</b>	Configures an expert advanced ACL.
	<b>permit</b>	Adds a permit ACE to an expert advanced ACL.
	<b>deny</b>	Adds a deny ACE to an expert advanced ACL.
	<b>expert access-group in out</b>	Applies an expert advanced ACL
Configuring ACL Redirection	 (Optional) It is used to redirect packets meeting the rules to a specified interface.	
	<b>redirect destination interface acl in</b>	Configures ACL redirection.
Configuring a Global Security ACL	 (Optional) It is used to make an ACL take effect globally.	
	<b>ip access-group in out</b>	Applies a global security ACL in global configuration mode.
	<b>no global ip access-group</b>	Configures an interface as the exclusive interface of the global security ACL in interface configuration mode.
Configuring a Security Channel	 (Optional) It is used to enable packets meeting some characteristics to bypass the checks of access control applications, such as the DOT1X and Web authentication.	
	<b>security access-group</b>	Enables the security channel in interface configuration mode.
	<b>security global access-group</b>	Enables the security channel in global configuration mode.
	<b>security uplink enable</b>	Configures an interface as the exclusive interface of the global security channel in interface configuration mode.
Configuring Comments for ACLs	 (Optional) It is used to configure comments for an ACL or ACE so that users can easily identify the functions of the ACL or ACE.	
	<b>list-remark</b>	Configures a comment for an ACL in ACL configuration mode.
	<b>access-list list-remark</b>	Configures a comment for an ACL in global configuration mode.
	<b>remark</b>	Configures a comment for an ACE in ACL configuration mode.
Global Forwarding Plane Security ACL	 (Optional) It is used to apply the ACL to only hardware packets.	

Configuration Item	Description and Command
	<b>ip access-group in forward-plane</b> Configures global forwarding plane security ACL in global configuration mode.

### 1.5.1 Configuring an IP ACL

#### Configuration Effect

Configure and apply an IP ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny the entry of specific IPv4 packets to a network to control access of IP users to network resources.

#### Notes

N/A

#### Configuration Steps

##### ▾ Configuring an IP ACL

- (Mandatory) Configure an IP ACL if you want to control access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IP ACL takes effect only on the local device, and does not affect other devices on the network.

##### ▾ Adding ACEs to an IP ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv4 packets of the device are denied by default.

##### ▾ Applying an IP ACL

- (Mandatory) Apply an IP ACL to a specified interface if you want this ACL take effect.
- You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

#### Verification

- Use the following methods to verify the configuration effects of the IP ACL:
- Run the **ping** command to verify that the IP ACL takes effect on the specified interface. For example, if an IP ACL is configured to prohibit a host with a specified IP address or hosts in a specified IP address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access related network resources to verify that the IP ACL takes effect on the specified interface. For example, access the Internet or access the FTP resources on the network through FTP.

#### Related Commands

##### ▾ Configuring an IP ACL

<b>Command</b>	<b>ip access-list { standard   extended } {acl-name   acl-id }</b>
<b>Parameter</b>	<b>standard:</b> Indicates that a standard IP ACL is created.
<b>Description</b>	<b>extended:</b> Indicates that an extended IP ACL is created. <b>acl-name:</b> Indicates the name of a standard or an extended IP ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".

	<i>acl-id</i> : Indicates the ID that uniquely identifies a standard or extended IP ACL. If this option is configured, a numbered ACL is created. If a standard IP ACL is created, the value range of <i>acl-id</i> is 1–99 and 1300–1999. If an extended IP ACL is created, the value range of <i>acl-id</i> is 100–199 and 2000–2699.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure a standard or an extended IP ACL and enter standard or extended IP ACL configuration mode. If you want to control access of users to network resources by checking the source IP address of each packet, configure a standard IP ACL. If you want to control access of users to network resources by checking the source or destination IP address, protocol number, and TCP/UDP source or destination port, configure an extended IP ACL.

### ▾ Adding ACEs to an IP ACL

- Add ACEs to a standard IP ACL.

Use either of the following methods to add ACEs to a standard IP ACL:

<b>Command</b>	[ <i>sn</i> ] { <b>permit</b>   <b>deny</b> } { <b>host source</b>   <b>any</b>   <i>source source-wildcard</i> } [ <b>time-range</b> <i>time-range-name</i> ] [ <b>log</b> ]
<b>Parameter Description</b>	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><b>host source</b>: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log</b>: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	Standard IP ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in standard IP ACL configuration mode. The ACL can be a named or numbered ACL.

<b>Command</b>	<b>access-list</b> <i>acl-id</i> { <b>permit</b>   <b>deny</b> } { <b>host source</b>   <b>any</b>   <i>source source-wildcard</i> } [ <b>time-range</b> <i>tm-rng-name</i> ] [ <b>log</b> ]
<b>Parameter Description</b>	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 1300–1999.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><b>host source</b>: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within</p>

	<p>this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log:</b> Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	Standard IP ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs to a numbered IP ACL in global configuration mode. It cannot be used to add ACEs to a named IP ACL.

- Add ACEs to an extended IP ACL.

Use either of the following methods to add ACEs to an extended IP ACL:

<b>Command</b>	<pre>[ sn ] { permit   deny } protocol { host source   any   source source-wildcard } { host destination   any   destination destination-wildcard } [ [ precedence precedence [ tos tos ] ]   dscp dscp ] [ fragment ] [ fragment-ipid fragment-ipid ] [ time-range time-range-name ] [ log ]</pre>
<b>Parameter Description</b>	<p><b>sn:</b> Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit:</b> Indicates that the ACE is a permit ACE.</p> <p><b>deny:</b> Indicates that the ACE is a deny ACE.</p> <p><b>protocol:</b> Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p><b>host source:</b> Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><b>source source-wildcard:</b> Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>host destination:</b> Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the <b>any</b> keyword is configured, IP packets sent to any host are filtered.</p> <p><b>destination destination-wildcard:</b> Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p><b>any:</b> Indicates that IP packets sent to or from any host are filtered.</p> <p><b>precedence precedence:</b> Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p><b>tos tos:</b> Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p><b>dscp dscp:</b> Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p><b>ecn ecn:</b> Indicates that IP packets with the specified ecn field in the header are filtered.</p> <p><b>fragment:</b> Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p><b>fragment-ipid fragment-ipid:</b> Indicates that packets with the specified fragment ID field in the header are filtered.</p> <p><b>time-range time-range-name:</b> Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log:</b> Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	Extended IP ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in extended IP ACL configuration mode. The ACL can be a named or numbered ACL.

<b>Command</b>	<b>access-list</b> <i>acl-id</i> { <b>permit</b>   <b>deny</b> } <i>protocol</i> { <b>host</b> <i>source</i>   <b>any</b>   <i>source source-wildcard</i> } { <b>host</b> <i>destination</i>   <b>any</b>   <i>destination destination-wildcard</i> } [ [ <b>precedence</b> <i>precedence</i> [ <b>tos</b> <i>tos</i> ] ]   <b>dscp</b> <i>dscp</i> ] [ <b>fragment</b> ] [ <b>fragment-ipid</b> <i>fragment-ipid</i> ] [ <b>time-range</b> <i>time-range-name</i> ] [ <b>log</b> ]
<b>Parameter Description</b>	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 2000–1999.</p> <p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p><b>host source</b>: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>host destination</b>: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the <b>any</b> keyword is configured, IP packets sent to any host are filtered.</p> <p><i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p><b>any</b>: Indicates that IP packets sent to or from any host are filtered.</p> <p><b>precedence precedence</b>: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p><b>tos tos</b>: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p><b>dscp dscp</b>: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p><b>ecn ecn</b>: Indicates that IP packets with the specified ecn field in the header are filtered.</p> <p><b>fragment</b>: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p><b>fragment-ipid fragment-ipid</b>: Indicates that packets with the specified fragment ID field in the header are filtered.</p> <p><b>time-range time-range-name</b>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log</b>: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	Extended IP ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs to a numbered IP ACL in extended IP ACL configuration mode. It cannot be used to add ACEs to a named extended IP ACL.

## 📌 Applying an IP ACL

<b>Command</b>	<b>ip access-group</b> { <i>acl-id</i>   <i>acl-name</i> } { <b>in</b>   <b>out</b> } [ <b>counter-only</b>   <b>forward-plane</b>   <b>priority</b> ]
<b>Parameter Description</b>	<p><i>acl-id</i>: Indicates that a numbered standard or extended IP ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named standard or extended IP ACL will be applied to the interface.</p> <p><b>in</b>: Indicates that this ACL controls incoming IP packets of the interface.</p> <p><b>out</b>: Indicates that this ACL controls outgoing IP packets of the interface.</p>

	<p><b>counter-only:</b> Indicates that the counter ACL is enabled.</p> <p><b>forward-plane:</b> Indicates that ACL is only applied to the forwarding plane.</p> <p><b>priority:</b> Sets the highest priority for the ACL on the forwarding plane of SVI interface.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command makes an IP ACL take effect on the incoming or outgoing packets of a specified interface. The counter-only ACL only counts the number of matching packets and does not filter packets. In addition, the count only takes effect only to <b>permit</b> rules and does not take effect to <b>deny</b> rules in the ACL.

**Configuration Example**

**i** The following configuration example describes only ACL-related configurations.

**Configuring an IP ACL to Prohibit Departments Except the Financial Department from Accessing the Financial Data Server**

<p><b>Scenario</b> Figure 1- 3</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an IPACL.</li> <li>● Add ACEs to the IP ACL.</li> <li>● Apply the IP ACL to the outgoing direction of the interface connecting the financial data server.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#ip access-list standard 1 sw1(config-std-nacl)#permit 10.1.1.0 0.0.0.255 sw1(config-std-nacl)#deny 11.1.1.1 0.0.0.255 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/3 sw1(config-if-GigabitEthernet 0/3)#ip access-group 1 out</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>● On a PC of the R&amp;D department, ping the financial data server. Verify that the ping operation fails.</li> <li>● On a PC of the financial department, ping the financial data server. Verify that the ping operation succeeds.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#show access-lists</pre>

```

ip access-list standard 1
10 permit 10.1.1.0 0.0.0.255
20 deny 11.1.1.0 0.0.0.255

sw1(config)#show access-group
ip access-group 1 out
Applied On interface GigabitEthernet 0/3

```

## 1.5.2 Configuring an MAC Extended ACL

### Configuration Effect

Configure and apply an MAC extended ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny the entry of specific L2 packets to a network to control access of users to network resources based on L2 packets.

### Notes

N/A

### Configuration Steps

#### ✚ Configuring an MAC Extended ACL

- (Mandatory) Configure an MAC extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the MAC address of each user's PC.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The MAC extended ACL takes effect only on the local device, and does not affect other devices on the network.

#### ✚ Adding ACEs to an MAC Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming L2 Ethernet packets of the device are denied by default.

#### ✚ Applying an MAC extended ACL

- (Mandatory) Apply an MAC extended ACL to a specified interface if you want this ACL take effect.
- You can apply an MAC extended ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

### Verification

- Use the following methods to verify the configuration effects of the MAC extended ACL:
- If an MAC extended ACL is configured to permit or deny some IP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, an MAC extended ACL is configured to prevent a device interface from receiving IP packets (Ethernet type is 0x0800), run the **ping** command for verification.

- If an MAC extended ACL is configured to permit or deny some non-IP packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- You can also construct L2 packets meeting some specified characteristics to check whether the MAC extended ACL takes effect. Typically, prepare two PCs, construct and send L2 packets on one PC, enable packet capturing on another PC, and check whether packets are forwarded as expected (forwarded or blocked) according to the action specified in the ACEs.

## Related Commands

### ▾ Configuring an MAC Extended ACL

<b>Command</b>	<b>mac access-list extended</b> { <i>acl-name</i>   <i>acl-id</i> }
<b>Parameter Description</b>	<i>acl-name</i> : Indicates the name of an MAC extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i> : Indicates the ID that uniquely identifies an MAC extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 700–799.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure an MAC extended ACL and enter MAC extended ACL configuration mode. You can configure an MAC extended ACL to control users' access to network resources by checking the L2 information of Ethernet packets.

### ▾ Adding ACEs to an MAC Extended ACL

Use either of the following methods to add ACEs to an MAC extended ACL:

- Add ACEs in MAC extended ACL configuration mode.

<b>Command</b>	[ <i>sn</i> ]{ <b>permit</b>   <b>deny</b> }{ <b>any</b>   <b>host</b> <i>src-mac-addr</i> }{ <b>any</b>   <b>host</b> <i>dst-mac-addr</i> }[ <i>ethernet-type</i> ][ <b>cos</b> <i>cos</i> [ <b>inner</b> <i>cos</i> ]] [ <b>time-range</b> <i>tm-rng-name</i> ]
<b>Parameter Description</b>	<i>sn</i> : Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. <b>permit</b> : Indicates that the ACE is a permit ACE. <b>deny</b> : Indicates that the ACE is a deny ACE. <b>any</b> : Indicates that L2 packets sent from any host are filtered. <b>host</b> <i>src-mac-addr</i> : Indicates that IP packets sent from a host with the specified source MAC address are filtered. <b>any</b> : Indicates that L2 packets sent to any host are filtered. <b>host</b> <i>dst-mac-addr</i> : Indicates that IP packets sent to a host with the specified destination MAC address are filtered. <i>ethernet-type</i> : Indicates that L2 packets of the specified Ethernet type are filtered. <b>cos</b> <i>cos</i> : Indicates that L2 packets with the specified class of service ( <i>cos</i> ) field in the outer tag are filtered. <b>inner</b> <i>cos</i> : Indicates that L2 packets with the specified <i>cos</i> field in the inner tag are filtered. <b>time-range</b> <i>time-range-name</i> : Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.
<b>Command</b>	MAC extended ACL configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	Run this command to add ACEs in MAC extended ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an MAC extended ACL in global configuration mode.

<b>Command</b>	<b>access-list</b> <i>acl-id</i> { <b>permit</b>   <b>deny</b> } { <b>any</b>   <b>host</b> <i>src-mac-addr</i> } { <b>any</b>   <b>host</b> <i>dst-mac-addr</i> } [ <i>ethernet-type</i> ] [ <b>cos</b> <i>cos</i> [ <b>inner</b> <i>cos</i> ]] [ <b>time-range</b> <i>tm-rng-name</i> ]
<b>Parameter Description</b>	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 700–799.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><b>host</b> <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><i>hostsource</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><b>any</b>: Indicates that L2 packets sent to any host are filtered.</p> <p><b>host</b> <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p><b>cos</b> <i>cos</i>: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p> <p><b>inner</b> <i>cos</i>: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to add ACEs to a numbered MAC extended ACL in global configuration mode. It cannot be used to add ACEs to a named MAC extended ACL.

### 📌 Applying an MAC Extended ACL

<b>Command</b>	<b>mac access-group</b> { <i>acl-id</i>   <i>acl-name</i> } { <b>in</b>   <b>out</b> } [ <b>counter-only</b>   <b>priority</b> ]
<b>Parameter Description</b>	<p><i>acl-id</i>: Indicates that a numbered MAC extended IP ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named MAC extended IP ACL will be applied to the interface.</p> <p><b>in</b>: Indicates that this ACL controls incoming L2 packets of the interface.</p> <p><b>out</b>: Indicates that this ACL controls outgoing L2 packets of the interface.</p> <p><b>counter-only</b>: Indicates that the counter ACL is enabled.</p> <p><b>priority</b>: Sets the highest priority for the ACL on the forwarding plane of SVI interface.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command makes an MAC extended ACL take effect on the incoming or outgoing packets of a specified interface. The counter-only ACL only counts the number of matching packets and does not filter packets. In addition, the count only takes effect only to <b>permit</b> rules and does not take effect to <b>deny</b> rules in the ACL.

### Configuration Example

The following configuration example describes only ACL-related configurations.

### 📌 Configuring an MAC Extended ACL to Restrict Resources Accessible by Visitors

<p><b>Scenario</b></p> <p><b>Figure 1- 4</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an MAC extended ACL.</li> <li>● Add ACEs to the MAC extended ACL.</li> <li>● Apply the MAC extended ACL to the outgoing direction of the interface connected to the visitor area so that visitors are allowed to access Internet and the public server of the company, but prohibited from accessing the financial data server of the company. That is, visitors cannot access the server with the MAC address 00e0.f800.000d.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#mac access-list extended 700 sw1(config-mac-nacl)#deny any host 00e0.f800.000d sw1(config-mac-nacl)#permit any any sw1(config-mac-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#mac access-group 700 in</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>● On a visitor's PC, ping the financial data server. Verify that the ping operation fails.</li> <li>● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds.</li> <li>● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#show access-lists mac access-list extended 700  10 deny any host 00e0.f800.000d etype-any  20 permit any any etype-any sw1(config)#show access-group mac access-group 700 in Applied On interface GigabitEthernet 0/2</pre>

### 1.5.3 Configuring an Expert Extended ACL

#### Configuration Effect

Configure and apply an expert extended ACL to an interface to control incoming and outgoing packets of the interface based on the L2 and L3 information, and allow or prohibit the entry of specific packets to the network. In addition, you can configure an expert extended ACL to control all L2 packets based on the VLAN to permit or deny the access of users in some network segments to network resources. Generally, you can use an expert extended ACL if you want to incorporate ACEs of the IP ACL and MAC extended ACL into one ACL.

#### Configuration Steps

##### ▾ Configuring an Expert Extended ACL

- (Mandatory) Configure an expert extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the VLAN ID.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert extended ACL takes effect only on the local device, and does not affect other devices on the network.

##### ▾ Adding ACEs to an Expert Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming packets of the device are denied by default.

##### ▾ Applying an Expert Extended ACL

- (Mandatory) Apply an expert extended ACL to a specified interface if you want this ACL take effect.
- You can apply an expert extended ACL in the incoming or outgoing direction of a specified interface of an access, an aggregate, or a core device based on the distribution of users.

#### Verification

- Use the following methods to verify the configuration effects of the expert extended ACL:
- If IP-based access rules are configured in an expert extended ACL to permit or deny some IP packets, run the **ping** command to verify whether these rules take effect.
- If MAC-based access rules are configured in an expert extended ACL to permit or deny some L2 packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- If VLAN ID-based access rules are configured in an expert extended ACL to permit or deny some L2 packets in some network segments (e.g., to prevent communication between VLAN 1 users and VLAN 2 users), ping PCs of VLAN 2 on a PC of VLAN 1. If the ping operation fails, the rules take effect.

#### Related Commands

##### ▾ Configuring an Expert Extended ACL

<b>Command</b>	<b>expert access-list extended</b> { <i>acl-name</i>   <i>acl-id</i> }
<b>Parameter Description</b>	<i>acl-name</i> : Indicates the name of an expert extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i> : Indicates the ID of an expert extended ACL. If this option is configured, a numbered ACL is created. The value

	range of <i>acl-id</i> is 2700-2899.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure an expert extended ACL and enter expert extended ACL configuration mode.

### ▾ Adding ACEs to an Expert Extended ACL

Use either of the following methods to add ACEs to an expert extended ACL:

- Add ACEs in expert extended ACL configuration mode.

<b>Command</b>	<code>[sn]{permit deny}[protocol][ethernet-type][cos[out][inner in]][[VID[out][inner in]]]{source source-wildcard  host source   any}{host source-mac-address any } {destination destination-wildcard   host destination   any} {host destination-mac-address any} [[precedence precedence][tos tos]   [dscp dscp][ecn ecn]] [fragment][fragment-ipid fragment-ipid] [range lowerupper] [[udf udf-id header pos value mask]   [int-flag-a] [int-flag-b]] [time-range time-range-name]]</code>
<b>Parameter Description</b>	<p><b>sn</b>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><b>protocol</b>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p><b>ethernet-type</b>: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p><b>cos out</b>: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p> <p><b>cos inner in</b>: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p><b>VID out</b>: Indicates that L2 packets with the specified VLAN ID field in the outer tag are filtered.</p> <p><b>VID inner in</b>: Indicates that L2 packets with the specified VLAN ID field in the inner tag are filtered.</p> <p><b>source source-wildcard</b>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>host source</b>: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent from any host are filtered.</p> <p><b>host source-mac-address</b>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><b>any</b>: Indicates that L2 packets sent to any host are filtered.</p> <p><b>destination destination-wildcard</b>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p><b>host destination</b>: Indicates that IP packets sent to a host with the specified destination IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent to any host are filtered.</p> <p><b>host destination-mac-address</b>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><b>any</b>: Indicates that L2 packets sent to any host are filtered.</p> <p><b>precedence precedence</b>: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p><b>tos tos</b>: Indicates that IP packets with the specified the TOS field in the header are filtered.</p> <p><b>dscp dscp</b>: Indicates that IP packets with the specified the dscp field in the header are filtered.</p>

	<p><b>ecn</b> <i>ecn</i>: Indicates that IP packets with the specified ecn field in the header are filtered.</p> <p><b>fragment</b>: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p><b>fragment-ipid</b> <i>fragment-ipid</i>: Indicates that packets with the specified fragment ID field in the header are filtered.</p> <p><b>udf</b> <i>udf-id header pos value mask</i>: Indicates the customized fields.</p> <p><b>int-flag</b>: Indicates that the int flag field of the packets is filtered.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
<b>Command Mode</b>	Expert extended ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in expert extended ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an expert extended ACL in global configuration mode.

<b>Command</b>	<p><b>access-list</b> <i>acl-id</i> { <b>permit</b>   <b>deny</b> } [<i>protocol</i>] [<i>ethernet-type</i>] [ <b>cos</b> [<i>out</i>] [<i>inner in</i>] ] [ [ <b>VID</b> [<i>out</i>] [<i>inner in</i>] ] ] { <i>source source-wildcard</i>   <b>host</b> <i>source</i>   <b>any</b> } { <b>host</b> <i>source-mac-address</i>   <b>any</b> } { <i>destination destination-wildcard</i>   <b>host</b> <i>destination</i>   <b>any</b> } { <b>host</b> <i>destination-mac-address</i>   <b>any</b> } [ [ <b>precedence</b> <i>precedence</i> ] [ <b>tos</b> <i>tos</i> ]   [ <b>dscp</b> <i>dscp</i> ] [ <b>ecn</b> <i>ecn</i> ] ] [ <b>fragment</b> ] [ <b>fragment-ipid</b> <i>fragment-ipid</i> ] [ <b>range</b> <i>lowerupper</i> ] [ [ <b>udf</b> <i>udf-id header pos value mask</i> ] [ [ <b>int-flag-a</b> ] [ <b>int-flag-b</b> ] ] [ <b>time-range</b> <i>time-range-name</i> ] ]</p>
<b>Parameter Description</b>	<p><b>acl-id</b>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 2700-2899.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p><i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p><b>cos out</b>: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p> <p><b>cos inner in</b>: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p><b>VID out</b>: Indicates that L2 packets with the specified VLAN ID field in the outer tag are filtered.</p> <p><b>VID inner in</b>: Indicates that L2 packets with the specified VLAN ID field in the inner tag are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p><b>host source</b>: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent from any host are filtered.</p> <p><b>host source-mac-address</b>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><b>any</b>: Indicates that L2 packets sent to any host are filtered.</p> <p><i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p><b>host destination</b>: Indicates that IP packets sent to a host with the specified destination IP address are filtered.</p> <p><b>any</b>: Indicates that IP packets sent to any host are filtered.</p> <p><b>host destination-mac-address</b>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><b>any</b>: Indicates that L2 packets sent to any host are filtered.</p> <p><b>precedence precedence</b>: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p><b>tos tos</b>: Indicates that IP packets with the specified the TOS field in the header are filtered.</p> <p><b>dscp dscp</b>: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p><b>ecn ecn</b>: Indicates that IP packets with the specified ecn field in the header are filtered.</p>

	<p><b>fragment:</b> Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p><b>fragment-ipid</b> <i>fragment-ipid</i>: Indicates that packets with the specified fragment ID field in the header are filtered.</p> <p><b>udf</b> <i>udf-id header pos value mask</i>: Indicates the customized fields.</p> <p><b>int-flag:</b> Indicates that the int flag field of the packets is filtered.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to add ACEs to a numbered expert extended ACL in global configuration mode. It cannot be used to add ACEs to a named expert extended ACL.

- Add VXLAN inner 5-tuple ACEs in expert extended ACL mode.

<b>Command</b>	<code>[sn]{permit deny}vxlan protocol{source source-wildcard host source any}{destination destination-wildcard host destination   any} [tagged] [udp-dport dport] [time-range time-range-name]</code>
<b>Parameter Description</b>	<p><b>permit:</b> Indicates that an ACE is a permit ACE.</p> <p><b>deny:</b> Indicates that an ACE is a deny ACE.</p> <p><i>protocol:</i> Indicates the VXLAN inner IP protocol to be matched. The value range is [0, 255]. For the sake of convenience, the system provides abbreviations for the frequently used IP protocols to replace the specific IP protocols, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p><i>source source-wildcard:</i> Indicates that VXLAN packets need to match the inner source IP network segment.</p> <p><b>host source:</b> Indicates that VXLAN packets need to match the inner source IP address of a host.</p> <p><b>any:</b> Indicates that VXLAN packets can match any inner source IP address.</p> <p><b>tagged:</b> Indicates that VXLAN packets need to match the inner tag field. VXLAN packets do not need to match the tag field by default.</p> <p><b>udp-dport</b> <i>dport</i>: Indicates that VXLAN packets need to match the destination port ID. If this parameter is not set, VXLAN packets need to match the default destination port ID, that is, 4798.</p> <p><b>time-range</b> <i>time-range-name</i>: Indicates that the ACE is associated with a time range. This ACE takes effect only within the specified time range. For more details about the time range, see the time range configuration manual.</p>
<b>Command Mode</b>	Expert extended ACL list mode
<b>Usage Guide</b>	This command is used to configure ACEs of VXLAN packets in an ACL in expert ACL mode. This ACL can be a named ACL or numbered ACL.

### 📌 Applying an Expert Extended ACL

<b>Command</b>	<code>expert access-group { acl-id   acl-name } { in   out } [ counter-only   forward-plane   priority ]</code>
<b>Parameter Description</b>	<p><i>acl-id:</i> Indicates that a numbered expert extended ACL will be applied to the interface.</p> <p><i>acl-name:</i> Indicates that a named expert extended ACL will be applied to the interface.</p> <p><b>in:</b> Indicates that this ACL controls incoming L2 packets of the interface.</p> <p><b>out:</b> Indicates that this ACL controls outgoing L2 packets of the interface.</p> <p><b>counter-only:</b> Indicates that the counter ACL is enabled.</p> <p><b>forward-plane:</b> Indicates that ACL is only applied to the forwarding plane.</p> <p><b>priority:</b> Sets the highest priority for the ACL on the forwarding plane of SVI interface.</p>

<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>This command makes an expert extended ACL take effect on the incoming or outgoing packets of a specified interface.</p> <p>The counter-only ACL only counts the number of matching packets and does not filter packets. In addition, the count only takes effect only to permit rules and does not take effect to deny rules in the ACL.</p>

**Configuration Example**

**i** The following configuration example describes only ACL-related configurations.

**Configuring an Expert Extended ACL to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)**

<p><b>Scenario</b> <b>Figure 1- 5</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an expert extended ACL.</li> <li>● Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2.</li> <li>● Add an ACE to prevent visitors from accessing the financial data server of the company.</li> <li>● Add an ACE to permit all packets.</li> <li>● Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.</li> </ul>
<p><b>SW1</b></p>	<pre> sw1(config)#expert access-list extended 2700 sw1(config-exp-nacl)#deny ip any any 192.168.1.0.0.0.255 any sw1(config-exp-nacl)#deny ip any any host 10.1.1.1 any sw1(config-exp-nacl)#pemit any any any any sw1(config-exp-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#expert access-group 2700 in                     </pre>

<b>Verification</b>	<ul style="list-style-type: none"> <li>● On a visitor's PC, ping the financial data server. Verify that the ping operation fails.</li> <li>● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds.</li> <li>● On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails.</li> <li>● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.</li> </ul>
<b>SW1</b>	<pre>sw1(config)#show access-lists expert access-list extended 2700  10 deny ip any any 192.168.1.0.0.255 any  20 deny ip any any host 10.1.1.1 any  30 permit ip any any any any  sw1(config)#show access-group expert access-group 2700 in Applied On interface GigabitEthernet 0/2</pre>

#### 1.5.4 Configuring an IPv6 Extended ACL

##### Configuration Effect

Configure and apply an IPv6 ACL to an interface to control all incoming and outgoing IPv5 packets of this interface. You can permit or deny the entry of specific IPv6 packets to a network to control access of IPv6 users to network resources.

##### Configuration Steps

###### ▾ Configuring an IPv6 ACL

- (Mandatory) Configure an IP ACL if you want to access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

###### ▾ Adding ACEs to an IPv6 ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv6 packets of the device are denied by default.

###### ▾ Applying an IPv6 ACL

- (Mandatory) Apply an IPv6 ACL to a specified interface on a device if you want this ACL take effect.
- You can apply an IPv6 ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

##### Verification

- Use the following methods to verify the configuration effects of the IPv6 ACL:

- Run the **ping** command to verify that the IPv6 ACL takes effect on the specified interface. For example, if an IPv6 ACL is configured to prohibit a host with a specified IP address or hosts in a specified IPv6 address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access network resources, for example, visit an IPv6 website, to check whether the IPv6 ACL takes effect on the specified interface.

## Related Commands

### ▾ Configuring an IPv6 ACL

<b>Command</b>	<b>ipv6 access-list <i>acl-name</i></b>
<b>Parameter</b>	<i>acl-name</i> : Indicates the name of a standard or an extended IP ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
<b>Description</b>	
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure an IPv6 ACL and enter IPv6 configuration mode.

### ▾ Adding ACEs to an IPv6 ACL

- To filter TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

<b>Command</b>	<b>[sn] {permit   deny } protocol {src-ipv6-prefix/prefix-len   host src-ipv6-addr   any} {dst-ipv6-pfx/pfx-len   host dst-ipv6-addr   any} [op dstport   range lower upper] [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name] [log]</b>
<b>Parameter Description</b>	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p><b>host src-ipv6-addr</b>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p><b>any</b>: Indicates that IPv6 packets sent from any host are filtered.</p> <p><i>dst-ipv6-pfx/pfx-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p><b>host dst-ipv6-addr</b>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p><b>any</b>: Indicates that IPv6 packets sent to any host are filtered.</p> <p><i>op dstport</i>: Indicates that TCP or UDP packets are filtered based on the L4 destination port number. The value of the <b>op</b> parameter can be <b>eq</b> (equal to), <b>neq</b> (not equal to), <b>gt</b> (greater than), or <b>lt</b> (smaller than).</p> <p><b>range lower upper</b>: Indicates that TCP or UDP packets with the L4 destination port number in the specified range are filtered.</p> <p><b>dscp dscp</b>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p> <p><b>flow-label flow-label</b>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p>

	<p><b>fragment:</b> Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p> <p><b>time-range <i>time-range-name</i>:</b> Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log:</b> Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	IPv6 ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in IPv6 ACL configuration mode.

- To filter IPv6 packets except for the TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

<b>Command</b>	<code>[sn]{permit deny}protocol{src-ipv6-prefix/prefix-len host src-ipv6-addr any}{dst-ipv6-pfix/pfix-len host dst-ipv6-addr any}[dscp dscp][flow-label flow-label][fragment][time-range tm-rng-name][log]</code>
<b>Parameter Description</b>	<p><b>sn:</b> Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit:</b> Indicates that the ACE is a permit ACE.</p> <p><b>deny:</b> Indicates that the ACE is a deny ACE.</p> <p><b>protocol:</b> Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><b>src-ipv6-prefix/prefix-len:</b> Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p><b>host src-ipv6-addr:</b> Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p><b>any:</b> Indicates that IPv6 packets sent from any host are filtered.</p> <p><b>dst-ipv6-pfix/pfix-len:</b> Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p><b>host dst-ipv6-addr:</b> Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p><b>any:</b> Indicates that IPv6 packets sent to any host are filtered.</p> <p><b>dscp dscp:</b> Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p> <p><b>flow-label flow-label:</b> Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p> <p><b>fragment:</b> Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p> <p><b>time-range <i>time-range-name</i>:</b> Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p><b>log:</b> Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
<b>Command Mode</b>	IPv6 ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in IPv6 ACL configuration mode.

### 📌 Applying an IPv6 ACL

<b>Command</b>	<code>ipv6 traffic-filter <i>acl-name</i> { in   out } [ counter-only   forward-plane   priority ]</code>
<b>Parameter Description</b>	<p><b><i>acl-name</i>:</b> Indicates the name of an IPv6 ACL.</p> <p><b>in:</b> Indicates that this ACL controls incoming IPv6 packets of the interface.</p>

	<p><b>out:</b> Indicates that this ACL controls outgoing IPv6 packets of the interface.</p> <p><b>forward-plane:</b> Indicates that ACL is only applied to the forwarding plane.</p> <p><b>priority:</b> Sets the highest priority for the ACL on the forwarding plane of SVI interface.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command makes an IPv6 ACL take effect on the incoming or outgoing packets of the specified interface.

### Configuration Example

#### Configuring an IPv6 ACL to Prohibit the R&D Department from Accessing the Video Server

<p><b>Scenario</b></p> <p>Figure 1- 6</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an IPv6 ACL.</li> <li>● Add an ACE to the IPv6 ACL to prevent access to the video server.</li> <li>● Add an ACE to the IPv6 ACL to permit all IPv6 packets.</li> <li>● Apply the IPv6 ACL to the incoming direction of the interface connected to the R&amp;D department.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#ipv6 access-list dev_deny_ipv6video sw1(config-ipv6-nacl)#deny ipv6 any host 200::1 sw1(config-ipv6-nacl)#permit ipv6 any any sw1(config-ipv6-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6video in</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>● On a PC of the R&amp;D department, ping the video server. Verify that the ping operation fails.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#show access-lists  ipv6 access-list dev_deny_ipv6video 10 deny ipv6 any host 200::1 20 permit ipv6 any any</pre>

```
sw1(config)#show access-group
ipv6 traffic-filter dev_deny_ipv6video in
Applied On interface GigabitEthernet0/2
```

### 1.5.5 Configuring an ACL80

#### Configuration Effect

When the IP ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL with fixed matching fields cannot meet requirements, configure the ACL80 to customize the packet fields that need to be matched.

#### Configuration Steps

##### ✚ Configuring an Expert Advanced ACL

- (Mandatory) Configure an expert advanced ACL if you want to implement the ACL80 function. For details about how to configure the expert advanced ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert advanced ACL takes effect only on the local device, and does not affect other devices on the network.

##### ✚ Adding ACEs to an Expert Advanced ACL

- (Mandatory) Add ACEs to an expert advanced ACL to customize matching fields. If no ACE is added to the expert advanced ACL, the deny ACEs will drop all packets by default. For details about how to add an ACE to an expert advanced ACL, see the related descriptions.

##### ✚ Applying an Expert Advanced ACL

- (Mandatory) Apply an expert advanced ACL to a specified interface if you want this ACL take effect.
- You can apply an expert advanced ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

#### Verification

- Use the following methods to verify the configuration effects of the expert advanced ACL:
- Run the **ping** command to check whether the configurations take effect.
- Construct packets matching the ACEs to check whether ACEs take effect.

#### Related Commands

##### ✚ Configuring an Expert Advanced ACL

<b>Command</b>	<b>expert access-list advanced <i>acl-name</i></b>
<b>Parameter Description</b>	<i>acl-name</i> : Indicates the name of an expert advanced ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
<b>Command Mode</b>	Global configuration mode

<b>Usage Guide</b>	Run this command to configure an expert advanced ACL and enter expert advanced ACL configuration mode.
--------------------	--

### ▾ Adding ACEs to an Expert Advanced ACL

<b>Command</b>	<code>[sn] { permit   deny } hex hex-mask offset</code>
<b>Parameter Description</b>	<p><b>sn</b>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p><b>permit</b>: Indicates that the ACE is a permit ACE.</p> <p><b>deny</b>: Indicates that the ACE is a deny ACE.</p> <p><b>hex</b>: Indicates the customized matching rule expressed in hexadecimal format, for example, 00d0f800.</p> <p><b>hex-mask</b>: Indicates the matching mask.</p> <p><b>offset</b>: Indicates the start position of matching. For example, if the matching content is 00d0f800, the matching mask is 00ff0000, and start position is 6, the destination MAC address of each packet is compared. All packets whose second byte of the destination MAC address is d0 match this ACE.</p>
<b>Command Mode</b>	Expert advanced ACL configuration mode
<b>Usage Guide</b>	Run this command to add ACEs in expert advanced ACL configuration mode.

### ▾ Applying an Expert Advanced ACL

<b>Command</b>	<code>expert access-group acl-n { in   out } [ [ forward-plane ]   [ priority ] ]</code>
<b>Parameter Description</b>	<p><b>acl-id</b>: Indicates that a numbered expert advanced ACL will be applied to the interface.</p> <p><b>acl-name</b>: Indicates that a named expert advanced ACL will be applied to the interface.</p> <p><b>in</b>: Indicates that this ACL controls incoming L2 packets of the interface.</p> <p><b>out</b>: Indicates that this ACL controls outgoing L2 packets of the interface.</p> <p><b>forward-plane</b>: Indicates that ACL is only applied to the forwarding plane.</p> <p><b>priority</b>: Sets the highest priority for the ACL on the forwarding plane of SVI interface.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command makes an expert advanced ACL take effect on the incoming or outgoing packets of a specified interface.

### Configuration Example

 The following configuration example describes only ACL-related configurations.

#### ▾ Configuring an ACL80 to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)

<p><b>Scenario</b> <b>Figure 1- 7</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an expert advanced ACL.</li> <li>● Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2.</li> <li>● Add an ACE to prevent visitors from accessing the financial data server of the company.</li> <li>● Add an ACE to permit all packets.</li> <li>● Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#expert access-list advanced acl80-guest sw1(config-exp-dacl)#deny C0A801 FFFFFFFF 42 sw1(config-exp-dacl)#deny 0A010101 FFFFFFFF 42 sw1(config-exp-dacl)#permit 0806 FFFF 24 sw1(config-exp-dacl)#permit 0800 FFFF 24 sw1(config-exp-dacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#expert access-group acl80-guest in</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>● On a visitor's PC, ping the financial data server. Verify that the ping operation fails.</li> <li>● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds.</li> <li>● On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails.</li> <li>● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#show access-lists expert access-list advanced sss 10 deny C0A801 FFFFFFFF 42 20 deny 0A010101 FFFFFFFF 42 30 permit 0806 FFFF 24</pre>

	<pre>40 permit 0800 FFFF 24  expert access-group acl80-guest in  Applied On interface GigabitEthernet 0/2</pre>
--	---

### 1.5.6 Configuring ACL Redirection

#### Configuration Effect

Configure the ACL redirection function on a specified interface to directly redirect specified packets on the interface or all interfaces to a specified port for further forwarding.

#### Configuration Steps

##### ▾ Configuring an ACL

- (Mandatory) To implement ACL redirection, you must first configure an ACL, for example, an IP, MAC extended, or expert extended ACL. For details about how to configure an ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

##### ▾ Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, the ACL redirection function is not available. For details about how to add an ACE to an ACL, see the related descriptions.

##### ▾ Configuring ACL Redirection

- (Mandatory) Enable ACL redirection on a specified interface if you want to implement ACL redirection.
- You can configure the ACL redirection function on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

#### Verification

Send packets matching ACEs on the port where ACL redirection is enabled, and then use the packet capturing software on the destination port to check whether the ACL redirection function takes effect.

#### Related Commands

##### ▾ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ▾ Configuring ACL Redirection on Interface

<b>Command</b>	<b>redirect destination interface</b> <i>interface-name</i> <b>acl</b> { <i>acl-id</i>   <i>acl-name</i> } <b>in</b>
<b>Parameter Description</b>	<p><b>interface</b> <i>interface-name</i>: Indicates the name of the destination port for redirection.</p> <p><i>acl-id</i>: Indicates the ID of an ACL.</p> <p><i>acl-name</i>: Indicates the name of an ACL.</p> <p><b>in</b>: Indicates that incoming packets of the interface are redirected.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Run this command to redirect incoming packets of the interface that match ACEs to the destination port for further forwarding.

### Configuration Example

 The following configuration example describes only ACL-related configurations.

#### ▾ Enabling ACL Redirection to Redirect Packets Sent from the Host 10.1.1.1 to the Packet Capturing Device for Analysis

<b>Scenario</b> Figure 1- 8	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configures an IP ACL.</li> <li>Add an ACE to the IP ACL to permit packets sent from the host 10.1.1.1.</li> <li>Enable ACL redirection on the port Gi 0/1, and set the destination port to Gi 0/2.</li> </ul>
<b>SW1</b>	<pre>sw1(config)#ip access-list standard 1 sw1 (config-std-nacl)#permit host 10.1.1.1 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# redirect destination interface gigabitEthernet 0/2 acl 1</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Capture packets on PC2. Ping the video server on PC 1. Verify that ICMP requests sent from PC 1 are captured on PC 2.</li> </ul>
<b>SW1</b>	<pre>sw1#show access-lists ip access-list standard 1 10 permit host 10.1.1.1</pre>

```
sw1#show redirect interface gigabitEthernet 0/1
acl redirect configuration on interface gigabitEthernet 0/1
redirect destination interface gigabitEthernet 0/2 acl 1 in
```

### 1.5.7 Configuring a Global Security ACL

#### Configuration Effect

Configure a global security ACL to prevent internal PCs of a company from accessing illegal websites or prevent virus from attacking the company's internal network. You can also configure exclusive interfaces to allow specified departments of the company to access external websites.

#### Configuration Steps

##### ✚ Configuring an ACL

- (Mandatory) Configure an IP ACL if you want to protect the internal network globally. For details about the configuration method, see the earlier descriptions about the ACL.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

##### ✚ Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the global security ACL does not exist. For details about how to add an ACE to an ACL, see the related descriptions.

##### ✚ Configuring a Global Security ACL

- (Mandatory) Enable the global security function if you want to make the global security ACL take effect.
- You can configure a global security ACL on an access, an aggregate, or a core device based on the distribution of users.

#### Verification

On the internal network protected by the global security ACL, ping the website or device that are denied by ACEs to check whether the global security ACL takes effect.

#### Related Commands

##### ✚ Configuring an ACL

For details about the configuration method, see the earlier descriptions about the ACL.

##### ✚ Adding ACEs to an ACL

For details about the configuration method, see the earlier descriptions about the ACL.

##### ✚ Configuring a Global Security ACL

<b>Command</b>	{ ip   mac   expert } access-group <i>acl-id</i> { in   out }
<b>Parameter</b>	<i>acl-id</i> : Indicates the ID of an IP ACL.
<b>Description</b>	<b>in</b> : Filters the incoming packets of the device.

	<b>out:</b> Filters the outgoing packets of the device.
<b>Command</b>	Global configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	Run this command to enable the global security ACL so that the ACL takes effect on all L2 interfaces of the device.

↘ **Configuring an Exclusive Interface of the Global Security ACL**

<b>Command</b>	<b>no global ip access-group</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command</b>	Interface configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	Run this command to invalidate a global security ACL on a specified interface.

**Configuration Example**

**i** The following configuration example describes only ACL-related configurations.

↘ **Configuring a Global Security ACL to Prevent the R&D Department From Accessing the Server of the Sales Department but Allow the Sales Department to Access This Server**

<p><b>Scenario</b> Figure 1- 9</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an extended IP ACL "ip_ext_deny_dst_sale_server".</li> <li>● Add the ACE that prevents the device to forward packets to the destination host 10.1.1.3/24.</li> <li>● Configure the ACL "ip_ext_deny_dst_sale_server" as a global security ACL.</li> <li>● Configure the interface directly connected to the sales department as the exclusive interface of the global security ACL.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#ip access-list extended ip_ext_deny_dst_sale_server sw1(config-ext-nacl)# deny ip any host 10.1.1.3 sw1(config-ext-nacl)# exit sw1(config)#ip access-group ip_ext_deny_dst_sale_server in sw1(config)#int gigabitEthernet 0/1</pre>

	sw1(config-if-GigabitEthernet 0/1)# no global ip access-group
<b>Verification</b>	<ul style="list-style-type: none"> <li>● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds.</li> <li>● On the PCs of R&amp;D department 1 and R&amp;D department 2, ping the server of the sales department. Verify that the ping operations fail.</li> </ul>
	<pre>sw1#show access-lists ipaccess-listextendedip_ext_deny_dst_sale_server  10 deny ip any host 10.1.1.3  sw1#show running ..... ! ip access-group ip_ext_deny_dst_sale_server in ! ! ! ! ! ! ! ! ! ! interface GigabitEthernet 0/1   no global ip access-group ! .....</pre>

### 1.5.8 Configuring a Security Channel

#### Configuration Effect

Configure a security channel to enable packets meeting the security channel rules to bypass the checks of access control applications. Configure the security channel if an access control application (such as DOT1X) is enabled on an uplink interface of a user, but the user should be allowed to log in to a website to download some resources (for example, downloading the FSSU client) before the DOT1X authentication.

#### Configuration Steps

##### 📌 Configuring an ACL

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.

- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

#### ✚ Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured for an ACL, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

#### ✚ Configuring a Security Channel on a Specified Interface or Globally

- Configure a security channel on an interface if you want this security channel take effect on the interface. Configure a global security channel if you want this security channel take effect globally. You must configure either the interface-based security channel or the global security channel.

- You can configure a security channel on an access, an aggregate, or a core device based on the distribution of users.

#### ✚ Configuring an Exclusive Interface for the Global Security Channel

- (Optional) Configure an interface as the exclusive interface for the global security channel if you do not want the global security channel to take effect on this interface.

#### ✚ Configuring an Access Control Application

- (Optional) You can enable the DOT1X or Web authentication function to verify the security channel function.
- You can configure the access control function on an access, an aggregate, or a core device based on the distribution of users.

#### Verification

On a PC that is subject to the control of an access control application, ping the resources (devices or servers) that are allowed to bypass the check of the access control application to verify the configuration of the security channel.

#### Related Commands

##### ✚ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ✚ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ✚ Configuring a Security Channel on an Interface

<b>Command</b>	<b>security access-group {acl-id   acl-name }</b>
<b>Parameter Description</b>	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Run this command to configure a specified ACL as the security channel on the specified interface.

##### ✚ Configuring a Global Security Channel

<b>Command</b>	<b>security global access-group</b> {acl-id   acl-name }
<b>Parameter Description</b>	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure the specified ACL as the global security channel.

↘ **Configuring an Exclusive Interface for the Global Security Channel**

<b>Command</b>	<b>security uplink enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Run this command to configure the specified interface as the exclusive interface of the global security channel.

**Configuration Example**

The following configuration example describes only ACL-related configurations.

↘ **Enabling DOT1X Authentication and Configuring a Security Channel to Allow Users to Download the SU Software From the Server Before Authentication**

<p><b>Scenario</b> Figure 1- 10</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an expert extended ACL "exp_ext_esc".</li> <li>● Add an ACE to allow forwarding packets to the destination host 10.1.1.2.</li> <li>● Add an ACE to permit the DHCP packets.</li> <li>● Add an ACE to permit the ARP packets.</li> <li>● On the interface where DOT1X authentication is enabled, configure the ACL "exp_ext_esc" as the security channel.</li> </ul>
<p><b>SW1</b></p>	<pre>sw1(config)#expert access-list extended exp_ext_esc sw1(config-exp-nacl)# permit ip any any host 10.1.1.2 any</pre>

	<pre>sw1(config-exp-nacl)# permit 0x0806 any any any any any sw1(config-exp-nacl)#permit tcp any any any any eq 67 sw1(config-exp-nacl)#permit tcp any any any any eq 68 sw1(config)#int gigabitEthernet0/1 sw1(config-if-GigabitEthernet 0/1)# security access-group exp_ext_esc</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds.</li> <li>● On the PCs of R&amp;D department 1 and R&amp;D department 2, ping the server of the sales department. Verify that the ping operations fail.</li> </ul>
	<pre>sw1#show access-lists expert access-list extended exp_ext_esc  10 permit ip any any host 10.1.1.2 any  20 permit arp any any any any any  30 permit tcp any any any any eq 67  40 permit tcp any any any any eq 68.....  sw1#show running-config interface gigabitEthernet 0/1  Building configuration... Current configuration: 59 bytes  interface GigabitEthernet 0/1  security access-group exp_ext_esc</pre>

### 1.5.9 Configuring the Time Range-Based ACEs

#### Configuration Effect

Configure the time range-based ACEs if you want some ACEs to take effect or to become invalid in a specified period of time, for example, in some time ranges during a week.

#### Configuration Steps

##### 📌 Configuring an ACL

- (Mandatory) Configure an ACL if you want ACEs to take effect in the specified time range. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

➤ **Adding an ACE with the Time Range Specified**

- (Mandatory) Specify the time range when adding an ACE. For details about how to configure the time range, see the configuration manual related to the time range.

➤ **Applying an ACL**

- (Mandatory) Apply the ACL to a specified interface if you want to make ACEs take effect in the specified time range.
- You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

**Verification**

In the time range that the configured ACE takes effect or becomes invalid, run the **ping** command or construct packets matching the ACE to check whether the ACE takes effect or becomes invalid.

**Related Commands**

➤ **Configuring an ACL**

For details about the ACL configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

➤ **Adding an ACE with the Time Range Specified**

For details about the ACE configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

➤ **Applying an ACL**

For details about the command for applying an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

**Configuration Example**

**i** The following configuration example describes only ACL-related configurations.

➤ **Adding an ACE With the Time Range Specified to Allow the R&D Department to Access the Internet Between 12:00 and 13:30 Every Day**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure a time range named "access-internet", and add an entry of the time range between 12:00 and 13:30 every day.</li> <li>● Configure an IP ACL "ip_std_internet_acl".</li> <li>● Add an ACE to allow packets with the source IP address in the network segment 10.1.1.0/24, and associate this ACE with the time zone "access-internet".</li> <li>● Add an ACE to deny packets with the source IP address the network segment 10.1.1.0/24. Access to the Internet is not allowed except in the specified time range.</li> <li>● Add an ACE to permit all packets.</li> <li>● Apply the ACL to the outgoing direction of the interface connected to the breakout gateway.</li> </ul>
<b>SW1</b>	<pre> FS(config)# time-range access-internet FS(config-time-range)# periodic daily 12:00 to 13:30 FS(config-time-range)# exit sw1(config)# ip access-list standard ip_std_internet_acl sw1(config-std-nacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet sw1(config-std-nacl)# deny 10.1.1.0 0.0.0.255 sw1(config-std-nacl)# permit any sw1(config-std-nacl)# exit sw1(config)# int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ip access-group ip_std_internet_acl out </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Within the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&amp;D department. Verify that the website can be opened normally.</li> <li>● Beyond the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&amp;D department. Verify that the website cannot be opened.</li> </ul>
<b>SW1</b>	<pre> sw1#show time-range  time-range entry: access-internet (inactive)     periodic Daily 12:00 to 13:30  sw1#show access-lists  ip access-list standard ip_std_internet_acl     10 permit 10.1.1.0 0.0.0.255 time-range access-internet (inactive)     20 deny 10.1.1.0 0.0.0.255     30 permit any </pre>

```
sw1#show access-group
ip access-group ip_std_internet_acl out
Applied On interface GigabitEthernet 0/2
```

### 1.5.10 Configuring Comments for ACLs

#### Configuration Effect

During network maintenance, if a lot of ACLs are configured without any comments, it is difficult to distinguish these ACLs later on. You can configure comments for ACLs to better understand the intended use of ACLs.

#### Configuration Steps

##### ▾ Configuring an ACL

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

##### ▾ Configuring Comments for ACLs

- (Optional) Configure comments for ACLs so that it is easy to manage and understand the configured ACLs.

##### ▾ Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

##### ▾ Configuring Comments for ACEs

- (Optional) To facilitate understanding of a configured ACL, you can configure comments for ACEs in addition to comments for the ACL.

#### Verification

Run the **show access-lists** command on the device to display the comments configured for ACLs.

#### Related Commands

##### ▾ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

##### ▾ Configuring a Comment for an ACL

Use either of the following two methods to configure a comment for a specified ACE in the ACL:

<b>Command</b>	<code>[sn] remark <i>comment</i></code>
<b>Parameter Description</b>	<b><i>comment</i></b> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.

	sn: Indicates the ID of ACE
<b>Command Mode</b>	ACL configuration mode
<b>Usage Guide</b>	Run this command to configure the comment for a specified ACE in the ACL. If sn is not configured, the comment is configured for the last ACE.

<b>Command</b>	<b>access-list <i>acl-id</i> sn-remark <i>comment</i></b>
<b>Parameter Description</b>	<p><b><i>acl-id</i></b>: Indicates the ID of an ACL.</p> <p><b><i>comment</i></b>: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.</p> <p>sn: Indicates the ID of ACE</p>
<b>Command Mode</b>	Configuration mode
<b>Usage Guide</b>	Run this command to configure the comment for a specified ACE in the ACL. If sn is not configured, the comment is configured for the last ACE.

### ▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

### ▾ Configuring Comments for ACEs

Use either of the following two methods to configure a comment for an ACE:

<b>Command</b>	<b>Remark <i>comment</i></b>
<b>Parameter Description</b>	<b><i>comment</i></b> : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
<b>Command Mode</b>	ACL configuration mode
<b>Usage Guide</b>	Run this command to configure the comment for a specified ACE.

<b>Command</b>	<b>access-list <i>acl-id</i> remark <i>comment</i></b>
<b>Parameter Description</b>	<p><b><i>acl-id</i></b>: Indicates the ID of an ACL.</p> <p><b><i>comment</i></b>: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure the comment for a specified ACE.

### 1.5.11 Configuring Global Forwarding Plane Security ACL

#### Configuration Effect

Configure the global forwarding plane security ACL to filter only hardware packets.

#### Configuration Steps

##### ✚ Configuring an ACL

- (Mandatory) Configure an ACL first to apply the ACL to only hardware packets. For details about how to configure an ACL, see the descriptions about ACL configuration.
- You can configure the ACL on an access, aggregate, or core device based on the distribution of users. The ACL takes effect only on the local device, and does not affect other devices on the network.

##### ✚ Configuring an ACE

- (Optional) An ACL may contain no rules. If no rule is configured, all IP packets of global software are filtered. For details about how to configure an ACE, see the descriptions about ACE configuration.

##### ✚ Configuring a Global Forwarding Plane Security ACL

- (Mandatory) Enable the global forwarding plane security ACL function first so that the global forwarding plane security ACL takes effect only on hardware packets.
- You can configure the global forwarding plane security ACL function on an access, aggregate, or core device based on the distribution of users.

#### Verification

Test whether the ACL takes effect on the forwarding plane but not on the control plane.

#### Related Commands

##### ✚ Configuring an ACL

For details about how to configure an ACL, see the descriptions about ACL configuration.

##### ✚ Configuring an ACE

For details about how to configure an ACE, see the descriptions about ACE configuration.

##### ✚ Configuring a Global Forwarding Plane Security ACL

<b>Command</b>	<b>ip access-group <i>acl-id</i> { in   out } forward-plane</b>
<b>Parameter Description</b>	<i>acl-id</i> : Indicates the ID of an ACL.
<b>Command Mode</b>	Global configuration mode.
<b>Usage Guide</b>	Run this command to enable the global forwarding plane security ACL function, so that the ACL takes effect only on hardware.

#### Configuration Example

##### ✚ Configuring a Global Forwarding Plane Security ACL to Implement Global ACL on Forwarding Plane

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure an IP ACL 1.</li> <li>● Add a rule to the IP ACL to prevent destination host 10.1.1.3/24 from accessing the network.</li> <li>● Add a rule to the IP ACL to allow all host addresses to access the network.</li> <li>● Configure the IP ACL 1 as the global forwarding plane security ACL.</li> </ul>
<b>SW1</b>	<pre>sw1(config)#ip access-list standard 1 sw1(config-ext-nacl)# denyhost 10.1.1.3 sw1(config-ext-nacl)#permit any sw1(config-ext-nacl)#exit sw1(config)#ip access-group 1 in forward-plane</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Ping SW 1 from the PC at the IP address 10.1.1.3. Verify that the PC cannot ping SW 1 but can ping other IP addresses whose packets are forwarded by SW 1.</li> </ul>
	<pre>sw1#show access-lists ip access-list standard 1 10 deny host 10.1.1.3 20 permit any sw1#show running ..... ! ip access-group 1 in forward-plane!</pre>

## 1.6 Monitoring

### Clearing

Description	Command
Clears the ACL packet matching counters.	<b>clear counters access-list</b> [ <i>acl-id</i>   <i>acl-name</i> ]
Clears the counters of packets matching the deny ACEs.	<b>clear access-list counters</b> [ <i>acl-id</i>   <i>acl-name</i> ]

### Displaying

Description	Command
Displays the basic ACLs.	<b>show access-lists</b> [ <i>acl-id</i>   <i>acl-name</i> ] [summary]
Displays the redirection ACEs bound to a specified interface. If the interface is not specified, redirection ACEs bound to all interfaces are displayed.	<b>show redirect</b> [ <b>interface</b> <i>interface-name</i> ]
Displays the ACL configurations applied to an interface.	<b>show access-group</b> [ <b>interface</b> <i>interface-name</i> ]
Displays the IP ACL configurations applied to an interface.	<b>show ip access-group</b> [ <b>interface</b> <i>interface-name</i> ]

Displays the MAC extended ACL configurations applied to an interface.	<b>show mac access-group</b> [interface <i>interface-name</i> ]
Displays the expert extended ACL configurations applied to an interface.	<b>show expert access-group</b> [interface <i>interface-name</i> ]
Displays the IPv6 ACL configurations applied to an interface.	<b>show ipv6 traffic-filter</b> [interface <i>interface-name</i> ]
Displays the TCAM information or the specified TCAM information.	<b>show acl res</b> [ dev <i>dev-num</i> [ slot <i>slot-num</i> ]]

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the ACL running process.	<b>debug acl acld event</b>
Debugs the ACL clients.	<b>debug acl acld client-show</b>
Debugs the ACLs created by all ACL clients.	<b>debug acl acld acl-show</b>

## 2Configuring QoS

### 2.1 Overview

Quality of Service (QoS) indicates that a network can provide a good service capability for specified network communication by using various infrastructure technologies.

When the network bandwidth is sufficient, all data streams can be properly processed; when network congestion occurs, all data streams may be discarded. To meet users' requirements for different applications and different levels of service quality, a network must be able to allocate and schedule resources based on users' requirements and provide different levels of service quality for different data streams. To be specific, the network can process real-time and important data packets in higher priorities, and process non-real-time and common data packets in lower priorities and even discard the data packets upon network congestion.

The "doing the best" forwarding mechanism used by traditional networks cannot meet the requirements any longer and then QoS comes into being. QoS-enabled devices provide transmission QoS quality service. A transmission priority can be assigned to data streams of a type to identify the importance of the data streams. Then, the devices provide forwarding policies for different priorities, congestion mitigation and other mechanisms to provide special transmission services for these data streams. A network environment configured with QoS can provide predictability for network performance, effectively allocate network bandwidth, and reasonably utilize network resources.

### 2.2 Applications

Application	Description
Interface Rate Limit + Priority Relabeling	Based on different service requirements for a campus network, provide rate control and priority-based processing for outgoing traffic of the teaching building, laboratories and dormitory building.
Priority Relabeling + Queue Scheduling	Provide priority-based processing and bandwidth control for traffic of internal access to servers of an enterprise.

#### 2.2.1 Interface Rate Limit + Priority Relabeling

##### Scenario

To meet the service requirements of normal teaching, a school puts forwards the following requirements:

- Control the Internet access traffic under 100M and discard packets out of control.
- Control the outgoing traffic of the dormitory building under 50M and discard packets out of control.
- Control the rate of packets with DSCP priority 7 sent from laboratories under 20M, and change the DSCP priorities of these packets whose rates exceed 20M to 16.
- Control the outgoing traffic of the teaching building under 30M and discard packets out of control.

Figure 2- 1

<b>Remarks</b>	A school connects GigabitEthernet0/24 of Switch A to the Internet in the uplink and connects GigabitEthernet0/1, GigabitEthernet0/2 and GigabitEthernet0/3 of Switch A to the teaching building, laboratory (192.168.195.0) and dormitory building (192.168.196.0) in the downlink respectively.
----------------	--

### Deployment

- Configure the QoS interface rate limit for the interface G0/24 of Switch A for connecting the Internet. Configure the QoS rate limit for packets sent from the dormitory building on Switch A.
- Set the rate limit for packets with the DSCP priority 7 sent from the laboratory to 20M and relabel the DSCP priority of packets out of the rate limit to 16.
- Configure the QoS rate limit for packets sent from the teaching building on Switch A.

### 2.2.2 Priority Relabeling + Queue Scheduling

#### Scenario

Configure priority relabeling and queue scheduling to meet the following requirements:

- When the R&D department and market department access servers, the priorities of the server packets are as follows: mail server > file server > salary query server.
- No matter when the HR management department accesses the Internet or servers, the switch processes the corresponding packets in the highest priority.
- Since network congestion often occurs in switch running, in order to ensure smooth business operation, WRR queue scheduling must be used to schedule IP packets for the R&D and market departments to access the mail database, file database, and salary query database based on the ratio of 6:2:1.

Figure 2- 2

<b>Remarks</b>	The R&D, market and HR management departments access the interfaces GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A respectively. The salary query server, mail server and file server are connected to GigabitEthernet 0/23 of Switch A.
----------------	--

### Deployment

- Configure the CoS values of data streams for accessing different servers to ensure that the switch processes packets for different servers in different priorities.
- Set the default CoS value of the interface to a specific value to ensure that the switch processes packets sent by the HR management department in the highest priority.
- Configure WRR queue scheduling to ensure that data packets are transmitted in a specific quantity ratio.

## 2.3 Features

### Basic Concept

#### DiffServ

The Differentiated Services (DiffServ) Mode is an IETF system based on which QoS is implemented in FS products. The DiffServ system classifies all packets transmitted in a network into different types. The classification information is included in layer-2/3 packet headers, including 802.1P, IP and IP DSCP priorities.

In a DiffServ-compliant network, all devices apply the same transmission service policy to packets containing the same classification information and apply different transmission service policies to packets containing different classification information. Classification information of packets is either assigned by hosts or other devices in the network or assigned based on different application policies or different packet contents. Based on the classification information carried by packets, a device may provide different transmission priorities for different packet streams, reserve bandwidth for a kind of packet streams, discard certain packets with lower priorities, or take some other actions.

#### 802.1P (PRI) priority

The 802.1P priority is located at the header of a layer-2 packet with the 802.1Q header, and is used in scenarios where layer-3 headers do not need to be analyzed and QoS needs to be implemented at layer 2. Figure 2-3 shows the structure of a layer-2 packet.

Figure 2- 3

As shown in Figure 1-3, the 4-byte 802.1Q header contains 2-byte Tag Protocol Identifier (TPID) whose value is 0x8100 and 2-byte Tag Control Information (TCI). The first three bits of the TCI indicate the 802.1P priority.

➤ **IP priority (IP PRE) and DSCP priority**

The priorities of IP packets are identified by the IP PRE and DSCP priority. The Type Of Service (ToS) field of the IPv4 header comprises 8 bits; where the first three bits indicate the IP precedence (IP PRE), ranging from 0 to 7. RFC 2474 redefines the ToS field of the IPv4 header, which is called the Differentiated Services (DS) field. The Differentiated Services Code Point (DSCP) priority is identified by the first 6 bits (bits 0 to 5) of the DS field, and by the first 6 bits of the Traffic Class field in the IPv6 header. Figure 2-4 shows the locations of the IP PRE and DSCP priorities in IPv4/IPv6 packets.

Figure 2-4

➤ **CoS**

Class of Service (COS). FS products convert packet priorities into CoS values to identify the local priorities of the packets and determine the input queue ID when packets are sent from the output interface.

**Overview**

Feature	Description
Stream Classification	Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services.
Priority Labeling and Mapping	Label packet priorities with specified values and map the values to corresponding CoS values.
Traffic Supervision	Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and

	discard the traffic out of the limit or modify the priority of the traffic.
Congestion Management	Determine the sequence of data packets sent from an interface based on the priorities of the data packets and ensure that key services can be processed in time when congestion occurs.
Congestion Mitigation	Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

### 2.3.1 Stream Classification

Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services. Stream classification rules are used to distinguish different packets in the network and specify different QoS parameters for packets at different service levels.

#### Working Principle

Stream classification rules can be matching the PRE or DSCP priorities of IP packets or classifying packets by identifying packet content through an ACL. You can define the binding between multiple streams and stream behaviors by using commands to form policies which can be applied to interfaces for stream classification and processing.

#### 📌 QoS policy

A QoS policy comprises three elements: class, stream behavior and policy.

- Class
 

A class identifies streams and comprises the class name and class rules. You can define the class rules by using commands to classify packets.
- Stream behavior
 

Stream behaviors define the QoS actions taken for packets, including priority labeling and traffic supervision for packets.
- Policy
 

A policy binds a specific class and specific stream behaviors and comprises the policy name, names of the classes bound, and stream behaviors. You can bind a specified class and stream behaviors by using a QoS policy and apply the policy to one or more interfaces.

#### 📌 QoS logical interface group

You can specify a series of interfaces as a QoS logical interface group (including both APs and Ethernet interfaces) and associate policies with the logical interface group for QoS processing. Take rate limit for stream behaviors for example. For packets that meet the rate limit conditions, all interfaces in the same logical interface group share the bandwidth specified by the policy.

#### Related Configuration

##### 📌 Creating a class

No class is defined by default.

You can run the **class-map** command to create a class and enter the class configuration mode.

##### 📌 Matching an ACL

No rules are defined for a class by default.

In the class configuration mode, you can run the **match access-group** command to define a class rule as matching an ACL. You need to create ACL rules first.

#### ↘ **Creating a policy**

No policy is defined by default.

You can run the **policy-map** command to create a policy and enter the policy configuration mode.

#### ↘ **Associating a class**

A policy is not associated with any class by default.

In the policy configuration mode, you can run the **class** command to associate a class and enter the policy-class configuration mode.

#### ↘ **Binding a stream behavior**

A class is not bound to any stream behavior by default.

In the policy-class configuration mode, you can run the **set** command to modify the CoS, DSCP or VID values of a specified stream; where, the CoS value ranges from 0 to 7, the DSCP value ranges from 0 to 63 and the VID value ranges from 1 to 4094. You can run the **police** command to limit the bandwidth and process streams out of the limit for specified streams. The bandwidth limit ranges are determined by products. Run the **apply acl** command to apply the ACL associated with the class.

#### ↘ **Configuring a logical interface group**

No logical interface group is defined and an interface is not added to any logical interface group by default.

In the global configuration mode, you can run the **virtual-group** command to create a logical interface group. In the interface configuration mode, you can run the **virtual-group** command to add an interface to a logical interface group. If this logical interface group is not created, you can create the logical interface group and add the interface to the group. You can create 128 logical interface groups, ranging from 1 to 128.

#### ↘ **Applying a policy to an interface**

No policy is applied to an interface by default.

In the interface configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of the interface. In the global configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of all interfaces.

### **2.3.2 Priority Labeling and Mapping**

Priorities are used to label the scheduling weights of packets or the priorities of the packets in forwarding. Different packet types have different priority types including 802.1P(PRI), IP PRE and DSCP priorities. Priority labeling and mapping refer to labeling packet priorities with specified values and mapping the values to corresponding CoS values.

#### **Working Principle**

After data streams of packets enter a device interface, the device assigns priorities to the packets based on the trust mode configured for the interface. The following describes several trust modes:

- When the interface trust mode is untrust, which means not trusting the priority information carried in packets:

Modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

- When the interface trust mode is trusting CoS:

For packets carrying the 802.1Q tag, modify the CoS value according to the PRI value, CoS-DSCP mapping table, and DSCP-CO mapping table, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

For packets not carrying the 802.1Q tag, modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.

- When the interface trust mode is trusting DSCP:

For non-IP packets, the processing is the same as that for trusting CoS.

For IP packets, modify the CoS value according to the DSCP value of the packets and the DSCP-CoS mapping table and put the packets into queues based on the final CoS value.

- When the interface trust mode is trusting IP PRE:

For non-IPv4 packets, the processing is the same as that for trusting CoS.

For IPv4 packets, obtain and modify the DSCP priority of the packets according to the IP PRE value of the packets and the IP-PRE-DSCP mapping table, obtain the CoS value according to the DSCP-CoS mapping table, and then put the packets into queues based on the final CoS value.

- When the trust mode and the applied policy of an interface work together:

When the trust mode and the applied policy of an interface work together, the trust mode has a lower priority than the policy and the CoS priority can be obtained according to the DSCP-CoS mapping table.

If a policy is applied to the interface but the policy does not have a configuration for modifying the DSCP and CoS values, the processing will be performed based on the trust mode of the interface.

## Related Configuration

### ↘ Configuring the trust mode of an interface

The default trust mode of an interface is untrust.

In the interface configuration mode, run the **mls qos trust** command to modify the trust mode. The trust mode can be trusting CoS, trusting DSCP or trusting IP PRE.

### ↘ Configuring the default CoS value of an interface

The default CoS value of an interface is 0.

In the interface configuration mode, run the **mls qos cos** command to modify the default CoS value of the interface, which ranges from 0 to 7.

### ↘ Labeling the priority of streams

The priorities of streams are not relabeled by default.

In the policy-class configuration mode, run the **set** command to modify the CoS, DSCP and VID values of streams. The CoS value ranges from 0 to 7, the DSCP value ranges from 0 to 63, and the VID value ranges from 1 to 4094.

### ↘ **Configuring CoS-to-DSCP Map**

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the `mls qos map cos-dscp` command to configure the CoS-DSCP mapping. The DSCP value ranges from 0 to 63.

### ↘ **Configuring DSCP-to-CoS Map**

By default, DSCP 0 to 7 are mapped to CoS 0, DSCP 8 to 15 mapped to CoS 1, DSCP 16 to 23 mapped to CoS 2, DSCP 24 to 31 mapped to CoS 3, DSCP 32 to 39 mapped to CoS 4, DSCP 40 to 47 mapped to CoS 5, DSCP 48 to 55 mapped to CoS 6, and DSCP 56 to 63 mapped to CoS 7.

Run the `mls qos map dscp-cos` command to configure the DSCP-CoS mapping. The CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63.

## 2.3.3 Traffic Supervision

Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of packets. In addition, the total traffic of an interface can be monitored and the traffic out of the limit will be discarded.

### Working Principle

Traffic supervision is used to monitor the specification of traffic flowing into a network and conduct preset supervision actions based on different assessment results. These actions can be:

- Forwarding: Normally forward packets within the traffic limit.
- Discarding: discard packets out of the traffic limit.
- Changing the priority and forwarding: modify the priorities of packets out of the traffic limit and then forward the packets.

Directly discard packets out of the total traffic limit of an interface.

### Related Configuration

#### ↘ **Configuring the action to be conducted for traffic out of limit**

No action to be conducted for traffic out of limit is configured by default.

In the policy-class configuration mode, run the `police` command to configure the action to be conducted for traffic out of limit to discarding traffic out of limit, or modifying the CoS value or DSCP value. The traffic limit range is determined by products. When the traffic is out of the limit, you can modify the CoS value in the range of 0 to 7 and the DSCP value in the range of 0 to 63.

#### ↘ **Configuring the total traffic limit for an interface**

The total traffic limit for an interface is not configured by default.

In the interface configuration mode, run the `rate-limit` command to configure the total traffic limit for an interface in the input and output directions. The traffic limit range is determined by products.

## 2.3.4 Congestion Management

When the receiving rate of packets exceeds the sending rate of packets, congestion will occur on the sending interface. If no sufficient buffer is provided to store these packets, the packets may be lost. The congestion management mechanism determines the sequence of data packets to be sent from an interface based on the priorities of the data packets. The congestion management function allows

for congestion control by increasing the priorities of important data packets. When congestion occurs, the important data packets are sent in higher priorities to ensure that key services are implemented in time.

### Working Principle

A queue scheduling mechanism is used for congestion management and the process is as follows:

- After each packet passes all QoS processing in a switch, the packet will obtain a CoS value finally.
- At the output interface, the device classifies the packets into corresponding sending queues based on the CoS values.
- The output interface selects packets in a queue for sending based on various scheduling policies (SP, WRR, DRR, WFQ, SP+WRR, SP+DRR, SP+WFQ).

### ▾ Scheduling policy

The queue scheduling policies include SP, WRR, DRR, WFQ, SP+WRR, SP+DRR and SP+WFQ.

- Strict-Priority (SP) scheduling means scheduling packets strictly following queue IDs. Before sending packets each time, check whether a queue with the first priority has packets to be sent. If yes, the packets in this queue are sent first. If not, check whether a queue with the second priority has packets. Follow the same rules for packets in other queues.
- Weighted Round Robin (WRR) scheduling means scheduling queues in turn to ensure that all queues have certain service time. For example, a 1000Mbps interface has 8 output queues. The WRR configures a weighted value (5, 5, 10, 20, 20, 10, 20 and 10, which indicate the proportions of obtained resources) for each queue. This scheduling method ensures that a queue with the lowest priority is assigned with at least 50 Mbps bandwidth, which avoids that packets in the queue with the lowest priority are not served for long time when the SP scheduling method is used.
- Deficit Round Robin (DRR) scheduling is similar to the WRR, but applies weight values based on bytes, but not based on time slices.
- Weighted Fair Queueing (WFQ) scheduling provides dynamic and fair queuing and applies weighted values based on bytes, similar to the DRR. When encountering an empty queue, the DRR will shift to the next queue for transmission immediately. If a queue misses its transmission time, the queue must wait for the next time, which is the difference between the WFQ and DRR; therefore, the WFQ is more suitable for processing data packets with variable lengths than the DRR.
- SP+WRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the WRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, the packets in WRR queues can be sent.
- SP+WFQ scheduling means configuring the SP scheduling for one or more sending queues and configuring the WFQ scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, the packets in WFQ queues can be sent.
- SP+WFQ scheduling means configuring the SP scheduling for one or more sending queues and configuring the WFQ scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, the packets in WFQ queues can be sent.

### ▾ QoS multicast queue

On some products, interface queues are classified into unicast queues and multicast queues. There are 8 unicast queues. All known unicast packets enter corresponding unicast queues for forwarding based on their priorities. There are 1 to 8 multicast queues

(depending on products. Certain products do not support multicast queues). Except for known unicast packets, all packets (such as broadcast packets, multicast packets, unknown unicast packets, and mirroring packets) enter corresponding multicast queues for forwarding based on their priorities. Similar to unicast queues, you can configure priority mappings and scheduling algorithms for multicast queues. The **Cos-to-Mc-Queue** command can be used to configure mapping from priorities to multicast queues. At present, multicast queues support the SP, WRR and SP+WRR scheduling algorithms.

#### 📌 Scheduling policy and round robin weight for output queues on an interface

The scheduling policies and round robin weight for output queues are based on global configurations. Some products support both global configurations and interface-based configurations. Interface-based configurations have higher priorities than global configurations. The global scheduling policy works with the corresponding global round robin weight whereas the interface scheduling policy works with the interface round robin weight. If only the global scheduling policy or interface scheduling policy is configured but no corresponding round robin weights are configured, the default round robin weights will work with the scheduling policy.

#### 📌 Queue bandwidth

Some products allow for configuring the guaranteed minimum bandwidth and the limited maximum bandwidth for a queue. A queue configured with the guaranteed minimum bandwidth ensures that the bandwidth for this queue is not smaller than the configured value. A queue configured with the limited maximum bandwidth ensures that the bandwidth for this queue is not greater than the configured value and packets out of the bandwidth limit will be discarded. The bandwidth limits for unicast and multicast queues are configured together on some products whereas configured separately on some other products. In addition, some products allow for configuring bandwidth only for unicast queues.

#### 📌 Queue ECN

With the combination of the WERD technology and explicit congestion notification (ECN) technology, a terminal device can perceive network congestion and notify the source device of the congestion. Upon receiving the notification, the source device reduces the packet sending rate to prevent aggravated congestion.

-  Both the ECN and WRED functions must be configured to enable the queue ECN function.
-  After the queue ECN function is enabled (namely, the ECN field in packets is set to **01** or **10**), when queue congestion occurs, the device changes the ECN field to **CE (11)**, instead of discarding packets randomly according to the WRED template.
-  After the queue ECN function is enabled, the device sets the ECN field to **CE** only when the packet rate reaches the lower discarding threshold specified in the WRED template.

### Related Configuration

#### 📌 Configuring CoS-to-Queue Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the queues 1, 2, 3, 4, 5, 6, 7 and 8 respectively.

Run the **priority-queue cos-map** command to configure the CoS-to-queue mapping. The CoS value ranges from 0 to 7 and the queue value ranges from 1 to 8.

#### 📌 Configuring the scheduling policy for an output queue

By default, the scheduling policy for a global output queue is WRR and no scheduling policy is configured for an interface.

Run the **mls qos scheduler** command to configure the output scheduling policy for a queue. Configurable scheduling policies include SP, WRR and DRR. You can also run the **priority-queue** command to configure the scheduling policy as SP.

#### ↘ **Configuring the round robin weight corresponding to the WRR scheduling policy for an output queue**

By default, the weight of a global or interface-based queue is 1:1:1:1:1:1:1:1.

Run the **wrr-queue bandwidth** command to configure the round robin weight corresponding to the WRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means longer output time.

#### ↘ **Configuring the round robin weight corresponding to the DRR scheduling policy for an output queue**

By default, the weight of a global or interface-based queue is 1:1:1:1:1:1:1:1.

Run the **dr-queue bandwidth** command to configure the round robin weight corresponding to the DRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

#### ↘ **Configuring the round robin weight corresponding to the WFQ scheduling policy for an output queue**

By default, the weight of a global or interface-based queue is 1:1:1:1:1:1:1:1.

Run the **wfq-queue bandwidth** command to configure the round robin weight corresponding to the WFQ scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

#### ↘ **Configuring the bandwidth for a queue**

Run the **qos queue** command to configure the guaranteed minimum bandwidth and the limited maximum bandwidth for each queue. The queue value ranges from 1 to 8 and the guaranteed minimum bandwidth and limited maximum bandwidth value ranges are determined by products. Supported queue types are determined by products.

#### ↘ **Configuring the Queue ENC**

Run the **qos queue queue\_num ecn** command to enable ECN on all queues. (Queue range: 1 to 8)

### 2.3.5 Congestion Mitigation

Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

#### **Working Principle**

Mitigate congestion by effectively monitoring the network traffic and forecasting occurrence of congestion. Packets need to be discarded to mitigate congestion. Discarding policies include Tail-Drop, Random Early Detection (RED), and Weighted Random Early Detection (WRED).

#### ↘ **Tail-Drop**

Traditional packet loss policies include Tail-Drop. Tail-Drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue will be discarded until the congestion is removed.

#### ↘ **RED and WRED**

Hosts running TCP will decrease the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. In this way, Tail-Drop may cause TCP Global Synchronization. When a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion mitigation and slow startup state simultaneously, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks may appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest quantity and the highest quantity. When TCP global synchronization occurs, the connection bandwidth cannot be adequately used, which causes bandwidth waste.

To avoid this circumstance, you can use the RED/WRED packet discarding policy. This policy provides a mechanism for discarding packets in random, which avoids TCP global synchronization. When packets of a TCP connection are discarded and sent at a lower rate, packets of other TCP connections are still sent at higher rates. In this way, there are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

When WRED is used, you can set the lower threshold value and maximum discarding probability for a queue. When the queue length is smaller than the lower threshold value, WRED does not discard packets. When the queue length is between the higher and lower threshold values, WRED discards packets in random (the longer the queue length, the higher probability of packet discarding. There is a maximum discarding probability). When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special example of WRED. When all CoS values of an interface are mapped to the same lower and higher threshold values, WRED becomes RED.

## Related Configuration

### 📄 Enabling the WRED function

The default packet discarding policy is Tail-Drop.

You can run the **queueing wred** command to enable the WRED function.

### 📄 Configuring the lower threshold

When 2 groups of lower thresholds in the unit of percentage are supported, the default values are 100 and 80 (the number of threshold groups are determined by products). Some products support configuration in the unit of cell (the default value is determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect min-threshold** command to configure the lower thresholds in the unit of percentage for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The lower threshold ranges from 1 to 100.

In the interface configuration mode, you can run the **wrr-queue random-detect min-threshold cell** command to configure the lower thresholds in the unit of cell for packets discarded by WRED in each queue. The queue value range varies from products.

### 📄 Configuring the higher threshold

When 2 groups of lower thresholds in the unit of percentage are supported, the default values are 100 and 100 (the number of threshold groups are determined by products). Some products support configuration in the unit of cell (the default value is determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect max-threshold** command to configure the higher thresholds in the unit of percentage for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The higher threshold ranges from the minimum value of lower threshold to the maximum value of higher threshold.

In the interface configuration mode, you can run the **wrr-queue random-detect max-threshold cell** command to configure the higher thresholds in the unit of cell for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The higher threshold ranges from the minimum value of lower threshold to the maximum value of higher threshold.

When the queue length is smaller than the lower threshold, WRED does not discard packets. When the queue length is between the lower and higher thresholds, WRED discards packets in random.

#### ▾ **Configuring the maximum discarding probability**

When 2 groups of maximum discarding probabilities are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect probability** command to configure the maximum discarding probabilities for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The maximum discarding probability ranges from 1 to 100.

#### ▾ **Adjusting the average queue length for discarding probability**

When packets are forwarded, WRED determines the discarding probability based on the average queue length of the output queue.

When the queue length is between the lower threshold and higher threshold, WRED starts to discard packets randomly. A longer queue leads to a higher discarding probability that is less than the maximum discarding probability. When the queue length is greater than the higher threshold, packets are discarded at the maximum discarding probability.

By default, the average queue length is determined by products. You can configure the sampling interval and weight of to-be-discarded packets to affect the calculation result of the average queue length.

The sampling weight indicates the weight factor of sampled data updates. A larger sampling weight indicates a longer update interval of the average queue length and a larger average queue length. In interface configuration mode, you can run the **wrr-queue random-detect sample-weight** command to configure the sampling weight factor of each queue. The value range is determined by products.

#### ▾ **Configuring the CoS-to-threshold mapping**

By default, all CoS values are mapped to the first group of threshold values (the number of threshold groups is determined by products).

In the interface configuration mode, you can run the **wrr-queue cos-map** command to configure the CoS-to-threshold group mapping. The CoS value ranges from 0 to 7 and the number of threshold groups is determined by products. Multiple groups of lower threshold values and maximum discarding probabilities can be configured. By configuring the CoS-to-threshold group mapping, you can select the effective threshold group mapped to a CoS value, for example, CoS 0 mapped to the first threshold group, and CoS 1 mapped to the second threshold group. If the packets of CoS 0 and 1 are added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold values and maximum discarding probabilities in the first group and the packets of CoS 1 are processed based on the lower threshold values and maximum discarding probabilities of the second group.

When all CoS values of an interface are mapped to the same group of threshold values, the enabled WRED becomes RED.

### **2.3.6 Queue Display and Configuration**

By default, the display and configuration mode of all queues on the device is 1–8.

#### ▾ **Changing the queue display and configuration mode**

In global configuration mode, you can run the **qos-queue compatible enable** command to change the queue display and configuration mode of all queues on the device to 0–7.

### 2.3.7 Packet Priority Modification

By default, the priority of a packet is changed to that configured on a device when the packet is sent out from the device. For example, an L2 packet whose priority is 4 is sent. The ingress direction is associated with the policy-map. If the packet matches the policy, the CoS value in the packet is set to 2. When the packet is captured in the egress, the packet priority is 2.

#### ▾ Disabling packet priority modification

In global configuration mode, run the **mls qos remark disable** command to disable packet priority modification, that is, when a packet is sent out from a device, the priority of the packet is the same as that when the packet is sent to the device.

## 2.4 Limitations

- The QoS trust mode cannot be configured on SVIs.

- For the N5860/N8560/NC8200 series products, members of a logical port group must be on the same device.
- Members to be added to a logical port group must be physical ports or Aggregate Ports (APs).

The deny entry in an ACL matching a class-map does not take effect.

- The N5860/N8560/NC8200 series products do not support VID modification.

- When QoS is applied to the outbound direction, the N5860/N8560/NC8200 series products change the DSCP value of packets whose bandwidth exceeds the limit but keep the CoS value unchanged. When QoS is applied to the inbound direction, the N5860/N8560/NC8200 series products change the DSCP value and CoS value of packets whose bandwidth exceeds the limit.
- The N5860/N8560/NC8200 series products change both the DSCP value while changing the CoS value of packets whose bandwidth exceeds the limit. After **none-tos** is set, the N5860/N8560/NC8200 series products do not change the DSCP value when changing the CoS value.
- The N5860/N8560/NC8200 series products do not support the **none-tos** option when CoS is configured.
- On the N5860/N8560/NC8200 series products, bandwidth limit is based on the actual bandwidth, including the load generated by the preamble and interframe gap. The preamble and interframe gap carried in each packet occupy 20 bytes.
- The N5860/N8560/NC8200 series products support the minimum rate limit granularity of 8 Kbps. The rate limit granularity varies with the rate limit settings. The following table lists the relationships between rate limits and granularities.

Rate Limit Range	64 Kbps to 2 Gbps	2 Gbps to 4 Gbps	4 Gbps to 8 Gbps
Granularity	8 Kbps	16 Kbps	32 Kbps
Rate Limit Range	8 Gbps to 16 Gbps	16 Gbps to 32 Gbps	32 Gbps to 40 Gbps

Granularity	64 Kbps	128 Kbps	256 Kbps
-------------	---------	----------	----------

- For the second parameter (burst traffic) in the QoS rate-limit policy, if the parameter value is excessively small, the actual rate may be excessively small in the case of burst traffic. If the parameter value is excessively large, the actual rate may be excessively large. You can use the following recommended configuration as required:
  - (1) If the configured rate limit is smaller than 1024 Kbps, the recommended burst-size value is 1024 KBytes.
  - (2) If the configured rate limit is smaller than 10240 Kbps, it is recommended to set the burst-size value to be the same as the rate limit or use the maximum value (the allowable burst-size value of the products may be smaller than 10240 KBytes).
  - (3) If the configured rate limit is greater than 10240 Kbps, it is recommended to set the burst-size value to the allowable maximum value of the device.
- For the second parameter in the QoS rate-limit policy, when the rate limit is relatively large, the second parameter needs to be adjusted accordingly. Otherwise, the rate limit may be inaccurate.
 

For 10G or 40G ports, it is recommended to set the burst-size to 32 or a larger value.

- The N5860/N8560/NC8200 series products support applying the policy map to the outbound direction.

When a policy is applied to an AP of the N5860/N8560/NC8200 series products, member ports of the AP must meet the following condition so that the configured bandwidth limit is the bandwidth shared by all member ports of the AP: Member ports of the AP must belong to the same N5860/N8560/NC8200 device.

- On the N5860/N8560/NC8200 series products, a class-map needs to be associated with an ACL, and therefore all restrictions configured in an ACL are available to the QoS function. For details, see the ACL configuration guide.
- Policy maps cannot be applied to SVIs.
- Policy maps can be configured in the output direction but cannot be configured on APs.
- Policy maps configured in the output direction do not support re-marking the CoS value of packets. The CoS value of packets is not re-marked when the DSCP value of the packets is re-marked.
- QoS is not supported on logical port groups in the output direction.

- The Virtual Switching Link (VSL) ports of the N5860/N8560/NC8200 series products adopt the Strict Priority (SP) + Deficit Round Robin (DRR) scheduling algorithm by default. Queue 7 adopts the SP scheduling and the weights of other queues are all 1, which cannot be modified by users.

When the QoS egress rate limit is configured on the N5860/N8560/NC8200 series products, the first 32 ports do not share the rate limit with subsequent ports. As a result, QoS is applied to the SVIs. If a SVI contains the first 32 ports and subsequent ports, the egress rate limit is doubled for packets that are transmitted by the first 32 ports and subsequent ports.

For example, member ports of VLAN 1 contain Gi0/1, Gi/2, Gi0/33, and Gi0/34, and the QoS rate limit of 10 Mbps is applied to VLAN 1. The actual rate limit of packets that are transmitted by Gi0/1, Gi/2, Gi0/33, and Gi0/34 is actually 20 Mbps. Gi0/1 and Gi/2 share the rate limit of 10 Mbps while Gi0/33 and Gi0/34 share the rate limit of another 10 Mbps.

You can run only the **show run** command to check whether the WRED function is enabled globally.

- The lower threshold and maximum drop probability of a queue form one WRED configuration group. The number of supported WRED configuration groups varies with the limit. The N5860/N8560/NC8200 series products support a maximum of 120 WRED configuration groups.

It is not recommended that the configured number of WRED configuration groups exceed 120. The extra WRED configuration groups may result in improper running.

- If the lower threshold is 100%, the WRED function is disabled.

- The N5860/N8560/NC8200 series products support mapping configuration on physical ports.
- Administrators can configure the DSCP-CoS and CoS-threshold mappings to implement the DSCP-threshold mapping.
- Administrators can configure the CoS-threshold and CoS-queue mappings to implement the queue-threshold mapping.

## 2.5 Configuration

Configuration	Description and Command	
Configuring Stream Classification	(Optional) It is used to create stream classification information.	
	<b>class-map</b>	Creates a class.
	<b>match access-group</b>	Matches ACL rules.
	<b>policy-map</b>	Creates a policy.
	<b>class</b>	Associates a class.
	<b>police</b>	Binds the bandwidth limit for streams and the action for processing packets out of the limit.
	<b>set</b>	Binds the behaviors for modifying the CoS, DSCP and VID values of streams.
	<b>apply acl</b>	Applies the ACL
	<b>virtual-group</b>	Creates a logical interface group and adds interfaces to the logical interface group.
Configuring Priority Labeling and Mapping for Packets	(Optional) It is used to configure the trust mode, default CoS value and various mappings for an interface.	
	<b>mls qos trust</b>	Modifies the trust mode of an interface.
	<b>mls qos cos</b>	Modifies the default CoS value of the interface.
	<b>mls qos map cos-dscp</b>	Configures the CoS-to-DSCP mapping.
	<b>mls qos map dscp-cos</b>	Configures the DSCP-to-CoS mapping.
Configuring Interface Rate Limit	(Optional) It is used to configure the rate limit for an interface.	
	<b>rate-limit</b>	Configures the traffic limit for an interface.
Configuring Congestion Management	(Optional) It is used to configure the CoS-to-queue mapping, queue scheduling policies and round robin weight.	
	<b>priority-queue cos-map</b>	Configures the CoS-to-queue mapping.
	<b>priority-queue</b>	Configures the output scheduling policy for a

Configuration	Description and Command	
		queue to SP.
	<b>mls qos scheduler</b>	Configures the output scheduling policy for a queue.
	<b>wrr-queue bandwidth</b>	Configures the round robin weight corresponding to the WRR scheduling policy for an output queue.
	<b>drr-queue bandwidth</b>	Configures the round robin weight corresponding to the DRR scheduling policy for an output queue.
	<b>wfq-queue bandwidth</b>	Configures the round robin weight corresponding to the WFQ scheduling policy for an output queue.
	<b>qos queue</b>	Configures the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.
	<b>qos queue ecn</b>	Enables the queue ECN function.
Configuring Congestion Mitigation	 (Optional) It is used to prevent network congestion by setting packet discarding.	
	<b>queueing wred</b>	Enables the WRED function.
	<b>wrr-queue random-detect sample-weight</b>	Configure the sampling weight of packets to be discarded by WRED.
	<b>wrr-queue random-detect min-threshold</b>	Configures the lower threshold value for packets discarded by WRED.
	<b>wrr-queue random-detect max-threshold</b>	Configures the higher threshold for packets discarded by WRED (in the unit of percentage).
	<b>wrr-queue random-detect min-threshold cell</b>	Configures the lower threshold for packets discarded by WRED (in the unit of cell).
	<b>wrr-queue random-detect max-threshold cell</b>	Configures the higher threshold for packets discarded by WRED (in the unit of cell).
	<b>wrr-queue random-detect probability</b>	Configures the maximum discarding probability for packets discarded by WRED.
Configuring Queue Display and Configuration Mode	 (Optional) It is used to set the queue display and configuration mode of all queues on the device to 0–7.	
	<b>qos-queue compatible enable</b>	Enables the queue display and configuration mode of all queues on the device to 0–7.
Disabling Packet Priority Modification	 (Optional) It is used to disable packet priority modification.	
	<b>mls qos remark disable</b>	Disables packet priority modification.

### 2.5.1 Configuring Stream Classification

#### Configuration Effect

- Create a class and match classification rules.
- Create a policy, bind a class and stream behaviors, and associate with an interface.

### Notes

- The class and policy names cannot comprise more than 31 characters.
- Interface configurations allow for only AP and Ethernet interface configurations. Certain products support policies applied to SVI interfaces through the **service-policy** command. When both physical interfaces and SVI interfaces are configured with policies, the priority of the physical interfaces is higher than that of the SVI interfaces.
- If run the **service-policy** command in global configuration mode, policies will be applied to all interfaces which can be configured with policies.

### Configuration Steps

#### ▾ Creating a class and matching ACL rules

- Optional.
- Create a class. In the class configuration mode, match ACL, IP PRE or DSCP.

#### ▾ Creating a policy

- Optional.
- Create a policy. In the policy configuration mode, bind the class and stream behaviors.

#### ▾ Creating a logical interface group and adding interfaces to the logical interface group

- Optional.
- Create a logical interface group and add interfaces to the logical interface group.

#### ▾ Applying a policy to an interface

- Optional.
- Associate a configured policy with a specified interface or logical interface group.

### Verification

- Run the **show class-map** command to check whether the class is successfully created and whether rules are successfully matched.
- Run the **show policy-map** command to check whether the policy is successfully created and whether the class and stream behaviors are successfully bound.
- Run the **show mls qos interface** command to check whether the interface is associated with the policy.
- Run the **show virtual-group** command to check the interfaces in the logical interface group.
- Run the **show mls qos virtual-group** command to check whether the logical interface group is associated with the policy.

### Related Commands

#### ▾ Creating a class

Command	<code>class-map class-map-name</code>

<b>Parameter Description</b>	<i>class-map-name</i> : Indicates the name of a class to be created. The name cannot comprise more than 31 characters.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	-

#### ↘ Matching an ACL

<b>Command</b>	<b>match access-group</b> <i>access-list-number</i>
<b>Parameter Description</b>	<i>access-list-number</i> : Indicates the number of the ACL to be matched.
<b>Command Mode</b>	Class configuration mode
<b>Usage Guide</b>	-

#### ↘ Creating a policy

<b>Command</b>	<b>policy-map</b> <i>policy-map-name</i>
<b>Parameter Description</b>	<i>policy-map-name</i> : Indicates the name of a policy to be created. The name cannot comprise more than 31 characters.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	-

#### ↘ Associating a class

<b>Command</b>	<b>class</b> <i>class-map-name</i>
<b>Parameter Description</b>	<i>class-map-name</i> : Indicates the name of a class to be associated.
<b>Command Mode</b>	Policy configuration mode
<b>Usage Guide</b>	-

#### ↘ Binding the behaviors for modifying the CoS, DSCP and VID values of streams

<b>Command</b>	<b>set { ip dscp <i>new-dscp</i> [with cos <i>new-cos</i> <b>priority</b>]   cos <i>new-cos</i> [<b>priority</b>   <b>none-tos</b>]   vid <i>new-vid</i> }</b>
<b>Parameter Description</b>	<p><b>ip dscp <i>new-dscp</i></b>: Changes the DSCP value of streams to <i>new-dscp</i>, ranging from 0 to 63.</p> <p><b>with cos <i>new-cos</i> <b>priority</b></b>: Configures the queue priority (same as <b>priority</b>).</p> <p><b>cos <i>new-cos</i></b>: Changes the CoS value of streams to <i>new-cos</i>, ranging from 0 to 7.</p> <p><b>Priority</b>: Configures the queue priority but not the CoS value.</p> <p><b>none-tos</b>: Does not change the DSCP value of packets when changing the CoS value of the packets.</p> <p><b>vid <i>new-vid</i></b>: Changes the VLAN ID of streams to <i>new-vid</i>, ranging from 1 to 4094.</p>
<b>Command Mode</b>	Class configuration mode
<b>Usage Guide</b>	The availability of command <b>set ip dscp <i>new-dscp</i> with cos <i>new-cos</i> <b>priority</b></b> varies with the chip capability of products.

#### ↘ Applying ACL

<b>Command</b>	<b>apply acl</b>
<b>Parameter Description</b>	
<b>Command Mode</b>	Class configuration mode
<b>Usage Guide</b>	Only one ACL can be applied in one policy, and the behavior takes effect according to the ACL.

#### ▾ Binding the bandwidth limit for streams and the action for processing packets out of the limit

<b>Command</b>	<b>police</b> <i>rate-bps</i> <i>burst-byte</i> [ <b>exceed-action</b> { <b>drop</b>   <b>dscp</b> <i>new-dscp</i>   <b>cos</b> <i>new-cos</i> [ <b>none-tos</b> ] } ]
<b>Parameter Description</b>	<p><i>rate-bps</i>: Indicates the bandwidth limit per second (KBits). The value range is determined by products.</p> <p><i>burst-byte</i>: Indicates the burst traffic limit (Kbytes). The value range is determined by products.</p> <p><b>drop</b>: Discards packets out of the bandwidth limit.</p> <p><b>dscp</b> <i>new-dscp</i>: Changes the DSCP value of packets out of the bandwidth limit to <i>new-dscp</i>, ranging from 0 to 63.</p> <p><b>cos</b> <i>new-cos</i>: Changes the CoS value of packets out of the bandwidth limit to <i>new-cos</i>, ranging from 0 to 7.</p> <p><b>none-tos</b>: Does not change the DSCP value of packets when changing the CoS value of the packets.</p>
<b>Command Mode</b>	Class configuration mode
<b>Usage Guide</b>	-

#### ▾ Creating a logical interface group and adding interfaces to the logical interface group

<b>Command</b>	<b>virtual-group</b> <i>virtual-group-number</i>
<b>Parameter Description</b>	<i>virtual-group-number</i> : Indicates the logical interface group number, ranging from 1 to 128.
<b>Command Mode</b>	Create the logical interface group in the global configuration mode, add the interface to the logical interface group in the interface configuration mode. If no logical interface group exists, you need to create a logical interface group first and then add interfaces to the logical interface group.
<b>Usage Guide</b>	-

#### ▾ Applying a policy to an interface

<b>Command</b>	<b>service-policy</b> { <b>input</b>   <b>output</b> } <i>policy-map-name</i>
<b>Parameter Description</b>	<p><b>input</b>: Indicates the input direction of the interface.</p> <p><b>output</b>: Indicates the output direction of the interface.</p> <p><i>policy-map-name</i>: Indicates the name of the policy applied to the interface.</p>
<b>Command Mode</b>	Interface configuration mode/Global configuration mode/Logical port group mode
<b>Usage Guide</b>	-

### Configuration Example

#### ▾ Creating four stream classes and matching ACL, IP PRE and DSCP

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Create ACL rules.</li> <li>● Create four stream classes and match ACL, IP PRE and DSCP.</li> </ul>
	FS# configureterminal

	FS(config)# access-list 11 permit host 192.168.23.61
	FS(config)# class-map cmap1 FS(config-cmap)# match access-group 11 FS(config-cmap)# exit
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the created ACL rules and stream class rules are successful.</li> </ul>
	FS# show access-lists ip access-list standard 11 10 permit host 192.168.23.61
	FS# show class-map Class Map cmap1 Match access-group 11

## 2.5.2 Configuring Priority Labeling and Mapping for Packets

### Configuration Effect

- Configure the trust mode and default CoS value of an interface.
- Configure the CoS-to-DSCP and DSCP-to-CoS mappings.

### Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

### Configuration Steps

#### ↘ Configuring the trust mode and default CoS value of an interface

- Optional.
- In the interface configuration mode, configure the trust mode and default CoS value of an interface.

#### ↘ Configuring the CoS-to-DSCP and DSCP-to-CoS mappings

- Optional.
- Configure various mappings.

### Verification

- Run the **show mls qos interface** command to display the trust mode and default CoS value of the interface.
- Run the **show mls qos maps** command to display the CoS-to-DSCP and DSCP-to-CoS mappings.

### Related Commands

#### ↘ Configuring the trust mode of an interface

<b>Command</b>	<b>mls qos trust { cos   ip-precedence   dscp }</b>
----------------	---

<b>Parameter</b>	<b>cos</b> : Configures the trust mode of an interface to CoS.
<b>Description</b>	<b>ip-precedence</b> : Configures the trust mode of an interface to IP PRE. <b>dscp</b> : Configures the trust mode of an interface to DSCP.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	-

#### 📌 Configuring the default CoS value of an interface

<b>Command</b>	<b>mls qos cos default-cos</b>
<b>Parameter Description</b>	<b>default-cos</b> : Configures the default CoS value, ranging from 0 to 7. The default value is 0.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	-

#### 📌 Configuring CoS-to-DSCP MAP

<b>Command</b>	<b>mls qos map cos-dscp dscp1...dscp8</b>
<b>Parameter Description</b>	<b>dscp1...dscp8</b> : Indicates the DSCP values mapped to the CoS values. The default CoS values 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	-

#### 📌 Configuring DSCP-to-CoS MAP

<b>Command</b>	<b>mls qos map dscp-cos dscp-list to cos</b>
<b>Parameter Description</b>	<b>dscp-list</b> : Indicates the DSCP list mapped to the CoS values. The default DSCP 0~7 are mapped to CoS 0, DSCP 8~15 mapped to CoS 1, DSCP 16~23 mapped to CoS 2, DSCP 24~31 mapped to CoS 3, DSCP 32~39 mapped to CoS 4, DSCP 40~47 mapped to CoS 5, DSCP 48~55 mapped to CoS 6, and DSCP 56~63 mapped to CoS 7. The DSCP value ranges from 0 to 63. <b>cos</b> : Indicates the CoS values mapped to the dscp-list, ranging from 0 to 7.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	-

### Configuration Example

#### 📌 Configuring the trust mode and default CoS value of an interface

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Modify the trust mode of the interface gigabitEthernet 0/0 to DSCP.</li> <li>● Change the default CoS value of the interface gigabitEthernet 0/1 to 7.</li> </ul>
	<pre>FS# configure terminal FS(config)# interface gigabitEthernet 0/0 FS(config-if-GigabitEthernet 0/0)# mls qos trust dscp</pre>

	<pre>FS(config-if-GigabitEthernet 0/0)# exit FS(config)# interface gigabitEthernet 0/1 FS(config-if-GigabitEthernet 0/1)# mls qos cos 7 FS(config-if-GigabitEthernet 0/1)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the trust mode and default CoS value are successfully configured for the interface.</li> </ul>
	<pre>FS# show mls qos interface gigabitEthernet 0/0 Interface: GigabitEthernet 0/0 Ratelimit input: Ratelimit output: Attached input policy-map: Attached output policy-map: Default trust: dscp Default cos: 0 FS# show mls qos interface gigabitEthernet 0/1 Interface: GigabitEthernet 0/1 Ratelimit input: Ratelimit output: Attached input policy-map: Attached output policy-map: Default trust: none Default cos: 7</pre>

📌 **Configuring the CoS-to-DSCP and DSCP-to-CoS mappings**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure CoS-to-DSCP to map CoS 0, 1, 2, 3, 4, 5, 6, and 7 to DSCP 7, 14, 21, 28, 35, 42, 49, and 56 respectively.</li> <li>● Configure DSCP-to-CoS to map DSCP 0, 1, 2, 3, and 4 to CoS 4 and DSCP 11, 12, 13 and 14 to CoS 7.</li> </ul>
	<pre>FS# configure terminal FS(config)# mls qos map cos-dscp 7 14 21 28 35 42 49 56</pre>
	<pre>FS(config)# mls qos map dscp-cos 0 1 2 3 4 to 4 FS(config)# mls qos map dscp-cos 11 12 13 14 to 7</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether all mappings are successfully configured.</li> </ul>

### 2.5.3 Configuring Interface Rate Limit

#### Configuration Effect

- Configure the traffic limit for an interface.

#### Notes

- The configuration is supported only by Ethernet interfaces.

#### Configuration Steps

### ▾ Configuring the traffic limit for an interface

- Optional.
- Configure the limit on the traffic and burst traffic for an interface.

#### Verification

- Run the **show mls qos rate-limit** command to display the rate limit information about the interface.

#### Related Commands

### ▾ Configuring the traffic limit for an interface

<b>Command</b>	<b>rate-limit { input   output } bps burst-size</b>
<b>Parameter</b>	<b>input:</b> Indicates the input direction of the interface.
<b>Description</b>	<b>output:</b> Indicates the output direction of the interface. <i>bps:</i> Indicates the bandwidth limit per second (Kbits). The value range is determined by products. <i>burst-size:</i> Indicates the burst traffic limit (Kbytes). The value range is determined by products.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	-

#### Configuration Example

### ▾ Typical application – Interface rate limit + priority relabeling

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● For Internet access by using the output interface, configure the output traffic limit on the interface G0/24, and set the bandwidth limit to 102,400 Kbits per second and burst traffic limit to 256 Kbytes per second.</li> <li>● For the dormitory building, configure the input traffic limit on the interface G0/3, and set the bandwidth limit to 51,200 Kbits per second and burst traffic limit to 256 Kbytes per second.</li> <li>● For the teaching building, configure the input traffic limit on the interface G0/1, and set the bandwidth limit to 30,720 Kbits per second and burst traffic limit to 256 Kbytes per second.</li> <li>● For the laboratory, create the class cmap_dscp7 to match DSCP priority 7, create the policy pmap_shiyan to associate with cmap_dscp7, bind the stream behavior of changing the DSCP value for packets whose rates exceed 20M to 16, apply pmap_shiyan to the interface G0/2, and configure the interface to trusting DSCP.</li> </ul>
	<pre> FS# configure terminal FS(config)# interface gigabitEthernet 0/24 FS(config-if-GigabitEthernet 0/24# rate-limit output 102400 256 FS(config-if-GigabitEthernet 0/24)# exit FS(config)# interface gigabitEthernet 0/3 FS(config-if-GigabitEthernet 0/3# rate-limit input 51200 256 FS(config-if-GigabitEthernet 0/3)# exit FS(config)# interface gigabitEthernet 0/1 FS(config-if-GigabitEthernet 0/1# rate-limit input 30720 256 FS(config-if-GigabitEthernet 0/1)# exit </pre>

## 2.5.4 Configuring Congestion Management

### Configuration Effect

- Configure the CoS-to-queue mapping.
- Configure the scheduling policy and round robin weight for an output queue.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.
- Enables the queue ECN function.

### Notes

- Interface configurations allow for only AP and Ethernet interface configurations.
- Both the ECN and WRED functions must be configured to enable the queue ECN function.

### Configuration Steps

#### ▾ Configuring the CoS-to-unicast and CoS-to-multicast mappings

- Optional.
- Configure the CoS-to-queue mappings. On products supporting multicast queues, you can configure the CoS-to-multicast queue mapping.

#### ▾ Configuring the scheduling policies and round robin weight for unicast and multicast output queues

- Optional.
- Configure the scheduling policy for an output queue and modify the round robin weight. On products supporting multicast queues, you can configure the scheduling policies and round robin weights for multicast queues.

#### ▾ Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

- Optional.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.
- Support global configuration mode and interface configuration mode. Function that these two modes support is different.

#### ▾ Enabling the queue ECN

- Optional.
- Enable the queue ECN function.

### Verification

- Run the **show mls qos queueing** command to display the output queue information.

<b>Command</b>	<b>qos queue [ ucast   mcast ] queue-id bandwidth { minimum   maximum } bandwidth</b>
<b>Parameter Description</b>	<p><b>queue [ ucast   mcast ]</b>: <b>queue ucast</b> configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring the unicast queue bandwidth limit; <b>queue mcast</b> configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring the multicast queue bandwidth limit; <b>queue</b> configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring both the unicast and multicast queue bandwidth limits.</p> <p><b>queue-id</b>: Indicates the queue ID to be configured, ranging from 1 to 8.</p> <p><b>minimum bandwidth</b>: Indicates the guaranteed minimum bandwidth Kbps. The value range is determined by products. It is not configured by default.</p> <p><b>maximum bandwidth</b>: Indicates the limited maximum bandwidth Kbps. The value range is determined by products. It is not configured by default.</p>
<b>Command Mode</b>	Interface/Global configuration mode
<b>Usage Guide</b>	-

### ▾ Enabling the queue ECN

<b>Command</b>	<b>qos queue queue-id ecn</b>
<b>Parameter Description</b>	<b>queue-id</b> : ID of the queue. Range: 1 to 8.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Both the ECN and WRED functions must be configured to enable the queue ECN function.

### Configuration Example

#### ▾ Configuring the CoS-to-queue mapping and modifying the scheduling policy and its round robin weight

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure the CoS-to-queue mapping to the mapping from the CoS values 0, 1, 2, 3, 4, 5, 6, and 7 to queues 1, 2, 5, 5, 5, 5, 7, and 8.</li> <li>Configure the output scheduling policy for a queue to DRR and the round robin weight to 2:1:1:1:6:6:6:8.</li> </ul>
	<pre> FS# configure terminal FS(config)#priority-queue cos-map 12555578 FS(config)# mls qos scheduler drr FS(config)# drr-queue bandwidth 2 1 1 1 6 6 6 8 </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Check whether the CoS-to-queue mapping is successfully created, and whether the output scheduling policy and round robin weight are successfully configured for the queue.</li> </ul>
	<pre> FS# show mls qos scheduler Global Multi-Layer Switching scheduling   Deficit Round Robin FS# show mls qos queueing CoS-to-queue map: </pre>

### 2.5.5 Configuring Congestion Mitigation

#### Configuration Effect

- Configure the lower and higher threshold value for WRED. When the length of packets in a queue is smaller than the lower threshold value, WRED does not discard packets.
- Configure the maximum discarding probability. When the length of packets in the queue is between the lower and higher threshold values, WRED discards packets in random. The maximum probability for discarding packets is configured.
- Configure the CoS-to-threshold mapping.

#### Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

#### Configuration Steps

##### ▾ Enabling the WRED function

- Optional.
- Enable the WRED function if necessary.

##### ▾ Configuring the lower threshold value

- Optional.
- Configure the lower threshold value if necessary.

### ✚ Configuring the higher threshold

- Optional.
- Configure the higher threshold if necessary.

### ✚ Configuring the maximum discarding probability

- Optional.
- Configure the maximum discarding probability if necessary.

### ✚ Adjusting the average queue length for discarding probability

- Optional.
- Configure the sampling interval and weight of the average queue length if necessary.

### ✚ Configuring the CoS-to-threshold mapping

- Optional.
- Configure the CoS-to-threshold mapping if necessary.

#### Verification

- Run the **show queueing wred interface** command to display the WRED configuration.
- Run the **show qos wred-ecn statistics** command to display the statistics of packets discarded by WRED and packets marked by ECN.

#### Related Commands

### ✚ Enabling the WRED function

<b>Command</b>	<b>queueing wred</b>
<b>Parameter</b>	-
<b>Description</b>	
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	-

### ✚ Configuring the lower threshold (in the unit of percentage)

<b>Command</b>	<b>wrr-queue random-detect min-threshold <i>queue_id</i> <i>thr1</i> [ <i>thr2</i> ]</b>
<b>Parameter</b>	<i>queue_id</i> : Indicates the queue ID for an interface, ranging from 1 to 8.
<b>Description</b>	<i>thrN</i> : Supports 2 groups of lower thresholds, ranging from 1 to the specified higher threshold.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Because the maximum value of the configuration range is equal to the current higher threshold, you need to pay attention to the setting of the higher threshold when configuring the lower threshold.  The threshold for packets to be discarded by WRED can be configured in the unit of percentage or cell. The latter configured mode prevails.

### ✚ Configuring the higher threshold (in the unit of percentage)

<b>Command</b>	<b>wrr-queue random-detect max-threshold</b> <i>queue_id thr1 [ thr2 ]</i>
<b>Parameter Description</b>	<i>queue_id</i> : Indicates the ID of a queue on an interface, ranging from 1 to 8. <i>thrN</i> : Supports 2 groups of higher thresholds, ranging from the specified lower threshold to 100.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Because the minimum value of the configured range is equal to the current lower threshold, you need to consider the lower threshold when configuring the higher threshold.  The threshold for packets to be discarded by WRED can be configured in the unit of percentage or cell. The latter configured mode prevails.

#### ↘ Configuring the lower threshold (in the unit of cell)

<b>Command</b>	<b>wrr-queue random-detect cell min-threshold</b> <i>queue_id thr1 [ thr2 ]</i>
<b>Parameter Description</b>	<i>queue_id</i> : Indicates the ID of a queue on an interface, ranging from 1 to 8. <i>thrN</i> : Supports 2 groups of lower thresholds, ranging from 1 to the specified higher threshold.  The default value is determined by products.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Whether this command is available is determined by products.  Because the maximum value of the configuration range is equal to the current higher threshold, you need to pay attention to the setting of the higher threshold when configuring the lower threshold.  The threshold for packets to be discarded by WRED can be configured in the unit of percentage or cell. The latter configured mode prevails.

#### ↘ Configuring the higher threshold (in the unit of cell)

<b>Command</b>	<b>wrr-queue random-detect cell max-threshold</b> <i>queue_id thr1 [ thr2 ]</i>
<b>Parameter Description</b>	<i>queue_id</i> : Indicates the ID of a queue on an interface, ranging from 1 to 8. <i>thrN</i> : Supports 2 groups of higher thresholds, ranging from the set lower threshold to the maximum higher threshold.  The default value is determined by products.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Whether this command is available is determined by products.  Because the minimum value of the configuration range is equal to the current lower threshold, you need to consider the lower threshold when configuring the higher threshold.  The threshold for packets to be discarded by WRED can be configured in the unit of percentage or cell. The latter configured mode prevails.

#### ↘ Configuring the maximum discarding probability

<b>Command</b>	<b>wrr-queue random-detect probability</b> <i>queue_id prob1 [ prob2 ]</i>
----------------	--

	<pre> FS(config-if-GigabitEthernet 0/2)#wrr-queue random-detect max-threshold 2 60 90 FS(config-if-GigabitEthernet 0/2)# wrr-queue random-detect probability 2 60 80 FS(config-if-GigabitEthernet 0/2)# wrr-queue random-detect probability 2 60 80 FS(config-if-GigabitEthernet 0/2)# wrr-queue cos-map 2 0 1 2 3                     </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the WRED function is enabled, whether the threshold values are successfully configured, and whether the CoS-to-threshold mapping is successfully configured.</li> </ul>

### 2.5.6 Configuring Queue Display and Configuration Mode

#### Configuration Effect

- Configure the queue display and configuration mode to change the display and configuration mode of all queues on the device from 1–8 to 0–7.

#### Notes

- After the queue display and configuration mode is configured, the configured queue-related commands change automatically.

#### Configuration Steps

##### ⌵ Setting the queue display and configuration mode to 0–7

- Optional.
- Set the queue display and configuration mode to 0–7 if necessary.

#### Verification

- Run the **show running-config** command to display the configurations.

#### Related Commands

##### ⌵ Setting the queue display and configuration mode to 0–7

## 2.5.7 Disabling Packet Priority Modification

### Configuration Effect

- After packet priority modification is disabled, the priority of a packet when it is sent out from a device is the same as that when the packet is sent to the device.

### Notes

### Configuration Steps

#### ▾ Disabling packet priority modification

- Optional.
- To ensure that the priority of a packet when it is sent out from a device is the same as that when it is sent to the device, disable packet priority modification.

### Verification

- Run the **show running-config** command to display the configurations.

## 2.6 Monitoring

### Clearing

Description	Command
Clear the statistics of packets discarded by WRED and packets marked by ECN.	<b>clear qos wred-ecn statistics [ interfaces <i>interface-id</i> ]</b>  For some products not supporting this command, run the clear queue-counter [ interfaces <i>interface-id</i> ] command.

### Displaying

Description	Command
Displays stream classification information.	<b>show class-map [ <i>class-map-name</i> ]</b>
Displays QoS policy information.	<b>show policy-map [ <i>policy-map-name</i> [ class <i>class-map-name</i> ] ]</b>
Displays the policy applied to an interface.	<b>show policy-map interface <i>interface-id</i></b>
Displays logical interface group information.	<b>show virtual-group [ <i>virtual-group-number</i>   summary]</b>
Displays the policy applied to a logical interface group.	<b>show mls qos virtual-group [ <i>virtual-group-number</i>   policers ]</b>
Displays various mappings.	<b>show mls qos maps [ cos-dscp   dscp-cos   ip-prec-dscp ]</b>
Displays interface rate limit information.	<b>show mls qos rate-limit [ interface <i>interface-id</i> ]</b>
Displays the QoS queue, scheduling policy and round robin weight information.	<b>show mls qos queueing [ interface <i>interface-id</i> ]</b>
Displays the scheduling information of an output queue.	<b>show mls qos scheduler [ interface <i>interface-id</i> ]</b>

Description	Command
Displays the configurations of WRED.	<b>show queueing wred interface</b> <i>interface-id</i>
Displays the QoS information of an interface.	<b>show mls qos interface</b> <i>interface-id</i> [ <b>policers</b> ]
Displays the bandwidth information of an interface.	<b>show qos bandwidth</b> [ <b>interfaces</b> <i>interface-id</i> ]
Display the statistics of packets discarded by WRED and packets marked by ECN.	<b>show qos wred-ecn statistics</b> [ <b>interfaces</b> <i>interface-id</i> ]

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the QoS library.	<b>debug qos lib</b> [ <b>event</b>   <b>message</b> ]
Debugs the QoS communication server.	<b>debug qos server</b> [ <b>event</b>   <b>message</b> ]
Debugs QoS user command processing.	<b>debug qos mls</b>
Debugs VMSUP configurations.	<b>debug qos vmsup</b>

## 3 Configuring MMU

### 3.1 Overview

The Memory Management Unit (MMU) means that the chip buffer is distributed reasonably so that the switching equipment can better deal with all kinds of burst flows.

Flows not steady all the time and various burst flows exist on the network. When the network flow is steady and the bandwidth is sufficient, all the data flows are processed better; when burst flows exist on the network, data flows may be discarded even if the average flow rate does not exceed the bandwidth.

Data packets that enter the switching equipment are stored in the buffer of switching equipment before being forwarded. Normally, data packets stay for a short period of time in the buffer and will be forwarded in microseconds; when there is a burst flow, if the instantaneous rate of burst flow exceeds the processing capacity of the switching equipment, the data packets that cannot be processed in time will be piled up in the switching equipment and packet loss will take place once the buffer is insufficient. In this case, the MMU can be used to reasonably configure the buffer and allocate different buffer sizes to respective services, with a view to optimizing the network.

### 3.2 Applications

Application	Description
Configuring Large Buffer Application Based on Egress Queue	An enterprise needs a buffer laFSe enough in the SkyDrive service to avoid packet loss for the service flow.
Configuring Large Buffer Application Based on Ingress PG	An enterprise needs to ensure no package loss in RDMA scenario. When the buffer reaches the threshold, PAUSE frame based on PFC mechanism should be generated to ensure no package loss.

#### 3.2.1 Configuring Large Buffer Application Based on Egress Queue

##### Scenario

An enterprise needs a buffer laFSe enough in the SkyDrive service to avoid packet loss for the service flow.

As shown in the following figure, equipment A is connected to 5 clients and 35 service servers, where 15 service servers virtualize 15 front end servers.

The main service flow is as follows:

- The client server sends a request packet to the front end server.
- The front end server sends the received request packet to the service server.
- After receiving the request packet, the service server sends a response packet to the front end server.
- After receiving the response packet, the front end server sends it to the client server.
- After receiving the response packet, the client indicates that a session is created successfully.

A many-to-one flow transmission mode exists under this service model:

- The request flows of multiple clients are sent to one front end server.
- The request flows of multiple front end servers are sent to one service server.

- The response flows of multiple service servers are sent to one front end server.
- The response flows of multiple front end servers are sent to one client.

These flows are transmitted through equipment A basically, easily leading to network congestion. Such a problem can be fixed by configuring a large buffer on the equipment.

Figure 3-1

### Deployment

- In all the service ports (namely, the ports connecting clients to servers), configure the shared buffer of the queue where the service is as 100%.
  - In all the service ports, configure the minimum value for the guaranteed buffer of the queue not in use.
  - In all the ports not in use, configure the minimum value for the guaranteed buffers of all the queues.
- i** For the specific configuration, see the configuration examples in "Configuration".

### 3.2.2 Configuring Large Buffer Application Based on Ingress PG

#### Scenario

A large enterprise needs to ensure no package loss in the data center. There are three kinds of flow in the data center:

- Storage flow: no package loss.
- High-performance computing flow: low delay.
- Ethernet flow: package loss and delay are allowed.

The traditional data center implements three networks for different flows, as shown below:

Figure 3-1

As the center scale expands, Ethernet is applied to take three kinds of flow and more mechanism is added so that it can meet different requirements, and storage package will not lose and have no effect on other 2 flows based on PFC (Priority-based Flow Control) of ingress PG.

### Deployment

- Map RDMA flow to a PG.
- Enable PFC on the PG to ensure no package loss of the flow.
- Configure xon/xoff threshold on the PG to generate flow control frame.
- For the PG not enabling PFC, the PG shared threshold should be higher than the egress threshold to ensure no packet loses on the ingress.
- For the PG enabling PFC, PG XOFF buffer threshold should be lower than the egress threshold to perform PFC function.
-  For more specific configuration, see Configuration Examples in Configuration.

## 3.3 Features

### Basic Concepts

#### 📄 Cell

Cell is a buffer unit, i.e., the minimum unit for the switching equipment to store packets. The size of each cell varies with the product. One packet can use multiple cells, while one cell can be used by only one packet.

#### 📄 Priority group (PG)

For the sake of better buffer management, BCM chip offers 8 PGs on the ingress direction for independent buffer management. Packets with different priorities (0-7) can be mapped to different PGs or one PG, so as to provide different buffer allocation scheme for packets with different priorities.

#### 📄 Egress queue

Port egress queues are classified into unicast queues and multicast queues. Logically the switching chip is divided into the ingress (incoming direction) and egress (outgoing direction). The egress queue is in the egress direction. Before packets go out of the egress, the enqueue operation needs to be performed for them at the egress queue. Some of our products implement buffer management based on the egress queue.

Figure 3-2

Currently there are three types of egress queue models:

- There are 8 unicast queues and 8 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are 8 unicast queues and 4 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are only 8 queues at the egress, without differentiating unicast and multicast.

#### Overview

Feature	Description
Buffer Adjustment	The buffer is adjusted based on the queue, PG and service pool. It is the foundation of MMU.
Status Monitoring	Status monitoring actually means monitoring the buffer use, and the number and rate of packets forwarded/discarded by the queue, which facilitates buffer adjustment.
Exception Alarm	Exception alarm analyses the device buffer and forwarding status, and displays the alarm when an exception occurs.

#### 3.3.1 Configuring Buffer Adjustment

Buffer adjustment means that the queue of each service has different buffer sizes through some adjustment of the queue buffer so that each service is treated differently and services at different priorities are served differently.

##### Working Principle

##### Working mechanism of caching in hardware

Buffer adjustment means that the queue of each service has different buffer availability through some adjustment of the chip buffer so that each service is treated differently and services at different priorities are served differently.

Figure 3-3

During buffer management, the input direction is adjusted to the maximum value to prevent packet loss in the input direction and make packet loss take place in the output direction. Therefore, adjustment is not opened for the buffer in the input direction, and CLI provides buffer adjustment in the output direction only, including the queue guaranteed buffer and queue shared buffer. Buffer adjustment configures the guaranteed buffer threshold and shared buffer threshold of queues to allocate different buffer sizes to queues.

↘ **Guaranteed buffer**

Guaranteed buffer is also called exclusive buffer. This part of buffer is distributed based on each queue. The guaranteed buffer of a queue can be used by this queue only. A fixed guaranteed buffer is allocated to each queue by default. This part of queue enables this queue to forward packets at the normal line rate under the stable flow.

↘ **Shared buffer**

In the total buffer of port group, the remaining part is the total shared buffer after the global guaranteed buffer and global headroom are deducted. The shared buffer can be allocated to one or several service pools. There is only one service pool (SP0) by default. On the input/output, a new shared service pool can be established by dividing room from SP0, and the mapping relationship between the input PG/output queue and the shared service pool can be configured respectively. A shared queue threshold can be set for each queue or PG. This threshold restricts the maximum shared buffer quantity that can be used by this queue. When the shared buffer

sum configured for each queue in the port group exceeds the total shared queue of port group, the "First Come First Served" buffer occupancy mechanism is adopted.

#### ↘ **Headroom buffer**

Headroom is the buffer on the ingress direction. PG that is enabled with flow control function will enter XOFF status after the guarantee and shared buffer runs out. To receive packets, it needs to use headroom buffer. Headroom is used to ensure no packet loss during the buffer flow control packet is sent and the rate decreases.

### 3.3.2 Configuring Status Monitoring

Status monitoring implements monitoring on the buffer use and the packet forwarding of each PG/queue, with a view to providing data support for network optimization and reasonable buffer configuration.

#### **Working Principle**

Status monitoring adopts the polling mode to read the buffer use amount and the number of packets forwarded/discarded by the queue, so as to display the equipment situation in real time.

#### ↘ **Buffer Occupancy on Ingress**

Collect the information of use of PG guaranteed/shared/headroom buffer on the ingress direction and the buffer occupancy of service pool at the fixed time, which can be checked by CLI, MIB or other methods.

#### ↘ **Buffer Occupancy on Egress**

Collect the information of use of PG guaranteed/shared/headroom buffer on the egress direction and the buffer occupancy of service pool at the fixed time, which can be checked by CLI, MIB or other methods.

#### ↘ **Packet Forwarding/Discarding of Egress Queue**

Collect the information of the number and byte of packets forwarded/discarded by the egress queue, and calculate the forwarding rate at the fixed time, which can be checked by CLI, MIB or other methods.

#### ↘ **Buffer monitoring data sampling interval**

Buffered monitoring data is sampled at a certain interval, and the interval can be configured based on user requirements.

#### ↘ **Slice ID Numbering Mode of MMU Buffer**

Configure the numbering mode of slice ID (start from 1 or 0), and switch the numbering mode of CLI/MIB.

### 3.3.3 Configuring Exception Alarm

Exception alarm monitors the packet forwarding and discarding of each queue, and displays alarms when the buffer exceeds threshold or packet losses.

#### **Working Principle**

The queue adopts the polling mode to read buffer occupancy and forwarding number of queue, and offers alarms by syslog based on the current configuration.

#### ↘ **Queue packet loss alarm**

The device analyzes statistics on discarded packets to judge whether packet loss occurs on a queue. After packet loss occurs on a queue, the device displays a packet loss alarm according to the packet loss alarm configuration.

#### ↘ Queue packet loss alarm frequency

Only  $N$  packet loss alarms can be displayed within a certain period of  $T$ . You can configure the period ( $T$ ) and number of alarms ( $N$ ) to adjust the display of packet loss alarms.

#### ↘ PG buffer utilization alarm threshold

When the buffer utilization of PG exceeds this threshold, syslog will be printed to remind the user.

#### ↘ Queue buffer utilization alarm threshold

When the buffer utilization of queue exceeds this threshold, syslog will be printed to remind the user.

#### ↘ MMU-HA buffer crash detection

The buffer management unit of chip may crash unexpectedly at runtime. MMU-HA analyzes buffer occupancy, queue forwarding, scheduling mode etc. to judge whether crash occurs. If crash occurs, it will display an alarm by syslog and the device will automatically restart.

### 3.4 Configuration

Configuration	Description and Command	
Buffer Adjustment	 (Optional) It is used to configure buffer.	
	<b>mmu queue-guarantee</b>	Configures guaranteed buffer.
	<b>mmu queue-threshold</b>	Configures shared buffer.
	<b>mmu buffer-mode</b>	Configures buffer mode.
	<b>mmu ingress-threshold</b>	Configures ingress PG shared buffer.
	<b>mmu xoff-threshold</b>	Configures ingress PG flow control threshold.
	<b>mmu xon-threshold-offset</b>	Configures ingress PG flow control restoration threshold.
	<b>mmu headroom-threshold</b>	Configures the PG-based headroom buffer size.
	<b>mmu pg-headroom</b>	Configures the global headroom buffer size.
	<b>mmu guarantee-limit</b>	Configures the global guaranteed buffer size.
	<b>mmu {ingress   egress} service-pool</b>	Configures the ingress/egress SP size.
	<b>mmu {priority-group   unicast-queue   multicast-queue } {id1[id2[idN]]} attach</b>	Configures the mapping relation between ingress PG/egress unicast/egress multicast and SP.
<b>mmu cut-through</b>	Configures cut-through transmission mode	
Status Monitoring	 (Optional) It is used to configure monitoring function.	
	<b>mmu sample-period</b>	Configures the buffer monitoring data sampling interval.
	<b>mmu slice-id compatible</b>	Configures the numbering mode of slice ID
Exception Alarm	 (Optional) It is used to detect exception.	

	<b>mmu usage-warn-limit</b>	Configures the buffer utilization alarm threshold.
	<b>mmu queue-loss-warn {unicast  multicast}</b>	Configures the queue packet loss alarm.
	<b>mmu queue-loss-warn frequency</b>	Configures the packet loss alarm frequency.
	<b>mmu ha</b>	Configures MMU-HA function/reset
	<b>mmu tcb-enable</b>	Configures the MMU-TCB function.

### 3.4.1 Configuring Buffer Adjustment

#### Configuration Effect

- Configure guaranteed buffer so that the PG/queue can use this part of buffer exclusively.
- Configure shared buffer so as to control the shared buffer use amount of the PG/queue.
- Configure PG headroom buffers so as to control the headroom buffer use amount of PG.
- Configure global guaranteed buffer so as to control the guaranteed buffer amount reserved for PG/queue.
- Configure global headroom buffer so as to control the headroom buffer amount reserved for PG.
- Configure the size of ingress/egress service pool to control the buffer amount allocated to the service pool.
- Configure the mapping relationships between PG/queue and service pool to allocate buffer from the specific pool.
- Configure the cut-through transmission mode to control whether the flow has MMU buffer allocation.

#### Notes

- Configuration in the interface mode can be made on the physical port only.

#### Configuration Steps

##### ▾ Configuring egress queue guaranteed buffer

- Optional.
- In interface configuration mode, use the **mmu queue-guarantee** command to configure guaranteed buffer for each queue and ensure that the buffer configuration range varies with the product.
- Use the **no** or **default** command of this command to restore the default value of buffer.

<b>Command</b>	<b>mmu queue-guarantee output { unicast   multicast } [queue-id1 [queue-id2 [queue-idN] ] set value</b>
<b>Parameter Description</b>	<b>output:</b> performs buffer management on the egress queue <b>unicast:</b> performs buffer management on the egress unicast queue <b>multicast:</b> performs buffer management on the egress multicast queue <i>queue-id:</i> queue ID, in the range from 1 to 8 <i>value:</i> number of guaranteed buffers, in cells; range: 1-100.
<b>Defaults</b>	8 cells
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The guaranteed buffer of all queues can not exceed the global guaranteed buffer.

##### ▾ Configuring egress queue shared buffer

- Optional.
- Use the **no** or **default** command of this command to restore the default value of buffer.

<b>Command</b>	<b>mmu queue-threshold output { unicast   multicast } [queue-id1 [queue-id2 [queue-idN] ] set {thr%   cell value}</b>
<b>Parameter Description</b>	<p><b>output:</b> performs buffer management on the egress queue</p> <p><b>unicast:</b> performs buffer management on the egress unicast queue</p> <p><b>multicast:</b> performs buffer management on the egress multicast queue</p> <p><i>queue-id:</i> queue ID, in the range from 1 to 8</p> <p><i>thr%:</i> percentage, in the range from 1 to 100</p> <p><i>cell:</i> configures the queue buffer as a static threshold of cell</p> <p><i>value:</i> the quantity of cells</p>
<b>Defaults</b>	100%
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	

### ▾ Configuring ingress PG guarantee buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu pg-guarantee pg { priority -id1 [priority-id2 [priority -idN] ] set value</b>
<b>Parameter Description</b>	<p><i>priority -idN:</i> ingress PG ID, range: 0-7</p> <p><i>Value:</i> guarantee buffer configuration value, range: 1-100.</p>
<b>Defaults</b>	The default value depends on the product.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The guaranteed buffer of all PGs can not exceed the global guaranteed buffer.

### ▾ Configuring ingress PG shared buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu ingress-threshold pg [pg-id0 [pg-id1 [pg-id N] ] set thr%</b>
<b>Parameter Description</b>	<p><i>pg-idN:</i> priority group ID, range: 0-7.</p> <p><i>thr%:</i> Total shared buffer x Threshold percentage = Maximum available buffer for the queue, range: 1-100</p>
<b>Defaults</b>	100%
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The effective way of this command varies with the product.</li> <li>2. The configuration takes effect only when flow control/Priority-based Flow Control (PFC) is not enabled.</li> <li>3. The user-configured value is displayed when the <b>show running-config</b> command is executed, even if the user-configured value is the default value.</li> </ol>

### ▾ Configuring ingress PG headroom buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu headroom-threshold pg [pg-id0 [pg-id1 [pg-id N] ] set value</b>
----------------	--

<b>Parameter</b>	<i>pg-idN</i> : priority group ID, range: 0-7.
<b>Description</b>	<i>Value</i> : headroom threshold value, in the unit of cell, range: 1-2000.
<b>Defaults</b>	The default value depends on the product.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The effective way of this command varies with the product.</li> <li>2. The configuration takes effect only when flow control/Priority-based Flow Control (PFC) is not enabled.</li> <li>3. The user-configured value is displayed when the <b>show running-config</b> command is executed, even if the user-configured value is the default value.</li> </ol>

#### ↘ Configuring flow control threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu xoff-threshold pg</b> [ <i>pg-id0</i> [ <i>pg-id1</i> [ <i>pg-id N</i> ] ] <b>set</b> <i>thr%</i>
<b>Parameter</b>	<i>pg-idN</i> : priority group ID, range: 0-7.
<b>Description</b>	<i>thr</i> : ingress PG XOFF threshold in the form of percentage, range: 1-100
<b>Defaults</b>	15%
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The effective way of this command varies with the product.</li> <li>2. The configuration takes effect only when flow control/PFC is enabled.</li> <li>3. If flow control/PFC is not enabled, the shared buffer threshold of the PG is according to the value of <b>ingress-threshold</b>.</li> <li>4. The user-configured value is displayed when the <b>show running-config</b> command is executed, even if the user-configured value is the default value.</li> </ol>

#### ↘ Configuring flow control restoration threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu xon-threshold-offset pg</b> [ <i>pg-id0</i> [ <i>pg-id1</i> [ <i>pg-id N</i> ] ] <b>set</b> <i>value</i>
<b>Parameter</b>	<i>pg-idN</i> : priority group ID, range: 0-7.
<b>Description</b>	<i>Value</i> : ingress PG XON threshold in the unit of cell, range: 1-500
<b>Defaults</b>	8 cells
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The effective way of this command varies with the product.</li> <li>2. The configuration takes effect only when flow control/PFC is enabled.</li> <li>3. The user-configured value is displayed when the <b>show running-config</b> command is executed, even if the user-configured value is the default value.</li> </ol>

#### ↘ Configuring global headroom threshold

- Optional.

- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu pg-headroom set value</b>
<b>Parameter Description</b>	<i>Value</i> : headroom threshold value, in the unit of cell, range: 1-20000.
<b>Defaults</b>	The default value depends on the product.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The effective way of this command varies with the product.</li> <li>2. The configuration takes effect only when flow control/PFC is enabled.</li> <li>3. The user-configured value is displayed when the <b>show running-config</b> command is executed, even if the user-configured value is the default value.</li> </ol>

#### ↘ Configuring size of global guaranteed buffer threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu guarantee-limit set value</b>
<b>Parameter Description</b>	<i>value</i> : limit of global guaranteed buffer, in the unit of cell.
<b>Defaults</b>	The default value depends on the product.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	The effective way of this command varies with the product.

#### ↘ Configuring size of shared service pool on the ingress/egress

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu {ingress egress} service-pool sp-id [name sp-name] set cell</b>
<b>Parameter Description</b>	Ingress: configure the shared service pool on the input egress: configure the shared service pool on the output sp-id: ID of the shared service pool, range: 0-3 cell: cell quantity of the shared service pool
<b>Defaults</b>	By default, all shared buffer space is allocated to SP0, and the size of SP1/2/3 is 0.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	The effective way of this command varies with the product. It is recommended to set the same size for shared service pools on the input/output for the same traffic, or packet loss may occur.

#### ↘ Configuring mapping relationship between input PG/output queue and shared service pool

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

<b>Command</b>	<b>mmu {priority-group  unicast-queue  multicast-queue} [id1 [id2 [idN]] attach sp-id</b>
<b>Parameter Description</b>	priority-group  unicast-queue  multicast-queue: configures the mapping relationship of input PG or output unicast/multicast queue idN: ID of the priority group (range: 0-7) or queue (range: 1-8) sp-id: ID of the shared service pool, range: 0-3
<b>Defaults</b>	All PG/queue is mapped to SP0.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	It is recommended to map the corresponding PG/queue to the same service pool to avoid abnormal packet loss.

### Verification

- Run the **show running-config** command to check the MMU configuration
- Run the **show queue-buffer** command to check the effect.

### Configuration Examples

#### ▾ Configuring guaranteed buffer of egress queue

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure 50 cells for the guaranteed buffer of unicast queue 1 in the interface mode.</li> <li>● Configure 30 cells for the guaranteed buffer of multicast queue 1 in the interface mode.</li> </ul>
	<pre> FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu queue-guarantee output unicast 1 set 50 FS(config-if-TFGigabitEthernet 0/1)# mmu queue-guarantee output unicast 1 set 30 FS(config-if-TFGigabitEthernet 0/1)#end FS# </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show this</b> command</li> </ul>
	<pre> FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration...  ! mmu queue-guarantee output unicast 1 set 50 mmu queue-guarantee output multicast 1 set 30 ! end FS(config-if-TFGigabitEthernet 0/1)# </pre>

#### ▾ Configuring shared buffer of egress queue

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure 80% of the dynamic threshold for the shared buffer of unicast queue 1 in the interface mode.</li> <li>● Configure the static threshold as 50000 cells for the shared buffer of unicast queue 2 in the interface mode.</li> </ul>
----------------------------	---

	<pre> FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu queue-threshold output unicast 1 set 80 FS(config-if-TFGigabitEthernet 0/1)# mmu queue-threshold output unicast 2 set cell 50000 FS(config-if-TFGigabitEthernet 0/1)# end FS# </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show this</b> command</li> </ul>
	<pre> FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu queue-threshold output unicast 1 set 80 mmu queue-threshold output unicast 2 set cell 50000 ! end FS(config-if-TFGigabitEthernet 0/1)# </pre>

#### ⌵ Configuring PG guaranteed buffer of ingress queue

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure 80 cells for the guaranteed buffer of PG 1 in the interface mode.</li> </ul>
	<pre> FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu pg-guarantee pg 1 set 80 FS(config-if-TFGigabitEthernet 0/1)#end FS# </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show this</b> command</li> </ul>
	<pre> FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu pg-guarantee pg 1 set 80 ! end FS(config-if-TFGigabitEthernet 0/1)# </pre>

### ▾ Configuring PG shared buffer on ingress queue

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 80% of the dynamic threshold for the shared buffer of PG 1 in the interface mode.</li> </ul>
	<pre> FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu ingress-threshold pg 1 set 80 FS(config-if-TFGigabitEthernet 0/1)#end FS# </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show this</b> command</li> </ul>
	<pre> FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu ingress-threshold pg 1 set 80 ! end FS(config-if-TFGigabitEthernet 0/1)# </pre>

### ▾ Configuring PG headroom buffer on ingress queue

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 500 cells for the headroom buffer of PG 1 in the interface mode.</li> </ul>
	<pre> FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu headroom-threshold pg 1 set 500 FS(config-if-TFGigabitEthernet 0/1)# end FS# </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show this</b> command</li> </ul>
	<pre> FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu headroom-threshold pg 1 set 500 ! end FS(config-if-TFGigabitEthernet 0/1)# </pre>

### ▾ Configuring flow control threshold

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 30% of the dynamic threshold for the flow control threshold of PG1 in the interface mode.</li> </ul>
	<pre>FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu xoff-threshold pg 1 set 30 FS(config-if-TFGigabitEthernet 0/1)# end FS#</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show this</b> command</li> </ul>
	<pre>FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu xoff-threshold pg 1 set 30 ! end FS(config-if-TFGigabitEthernet 0/1)#</pre>

### ▾ Configuring flow control restoration threshold

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 300 cells for the flow control restoration threshold of PG1 in the interface mode.</li> </ul>
	<pre>FS#config FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)# mmu xon-threshold-offset pg 1 set 300 FS(config-if-TFGigabitEthernet 0/1)# end FS#</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show this</b> command</li> </ul>
	<pre>FS(config-if-TFGigabitEthernet 0/1)#show this  Building configuration... ! mmu xon-threshold-offset pg 1 set 300 ! end FS(config-if-TFGigabitEthernet 0/1)#</pre>

### ↘ Configuring headroom threshold

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 10000 cells for the headroom threshold in the global configuration mode.</li> </ul>
	<pre>FS#config FS(config)# mmu pg-headroom set 10000 FS(config)# exit FS#</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show running-config</b> command</li> </ul>
	<pre>FS#show running-config   include mmu mmu pg-headroom set 10000 FS#</pre>

### ↘ Configuring global guaranteed buffer threshold

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure 10000 cells for the global guaranteed buffer in the global configuration mode</li> </ul>
	<pre>FS#config FS(config)# mmu guarantee-limit set 10000 FS(config)#exit FS#</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show running-config</b> command to check the configuration.</li> </ul>
	<pre>FS# show run       running-config   include mmu mmu guarantee-limit set 10000 FS#</pre>

### ↘ Configuring size of shared service pool on the input/output

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>In the global configuration mode, configure the size of input and output SP1 as 10000 cells.</li> </ul>
	<pre>FS# configure FS(config)# mmu ingress service-pool 1 set 10000 FS(config)# mmu egress service-pool 1 set 10000</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show running-config</b> command to check the configuration.</li> </ul>
	<pre>FS#show run       mmu ingress service-pool 1 set 10000       mmu egress service-pool 1 set 10000</pre>

	FS#
--	-----

↘ **Configuring mapping relationship between input PG/output queue and shared service pool**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure 10000 cells for the SP1 on the ingress/egress directions in the global configuration mode</li> <li>● Map ingress PG1 to ingress SP1, and map egress unicast/multicast queue 1 to the egress SP1 in the global configuration mode</li> </ul>
	<pre> FS# configure FS(config)# mmu ingress service-pool 1 set 10000 FS(config)# mmu egress service-pool 1 set 10000 FS(config)# mmu priority-group 1 attach service-pool 1 FS(config)# mmu unicast-queue 1 attach service-pool 1 FS(config)# mmu multicast-queue 1 attach service-pool 1 FS(config)# exit FS#                     </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show running-config</b> command to check the configuration.</li> </ul>
	<pre> FS#show running-config   include mmu mmu ingress service-pool 1 set 10000 mmu egress service-pool 1 set 10000 mmu priority-group 1 attach service-pool 1 mmu unicast-queue 1 attach service-pool 1 mmu multicast-queue 1 attach service-pool 1 FS#                     </pre>

**3.4.2 Configuring Buffer Monitoring**

**Configuration Effect**

- Configure the buffer utilization alarm threshold of port group. The log alarm will be printed when the buffer utilization of port group exceeds this configured value.
- Configure the buffer utilization alarm threshold of queue. The log alarm will be printed when the buffer utilization of queue exceeds this configured value.
- Configure the monitoring data sampling interval. The bottom layer samples and reports data according to the configured interval.
- Configure the numbering mode of slice ID starting from 1 or 0

**Notes**

- Configuration on the interface can be made on the physical port only.

**Configuration Steps**

↘ **Configuring the port group buffer utilization alarm threshold**

- Optional.
- In global configuration mode, use the **mmu usage-warn-limit** command to configure the buffer utilization alarm threshold for the port group.

- Use the **no** or **default** command of this command to restore the default setting.

<b>Command</b>	<b>mmu usage-warn-limit set value</b>
<b>Parameter</b>	<i>value</i> : percentage, range: 1-100
<b>Description</b>	
<b>Defaults</b>	The default value is 0, indicating that no alarm is reported.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This configuration takes effect for all the port groups.

#### ↘ Configuring the service pool buffer utilization alarm threshold

- Optional.
- In the interface configuration mode, use the **mmu usage-warn-limit {ingress-service-pool | egress-service-pool}** command to configure the buffer utilization alarm threshold for service pool.
- Use the **no** or **default** command of this command to restore the default settings.

<b>Command</b>	<b>mmu usage-warn-limit {ingress-service-pool   egress-service-pool} sp-id set value</b>
<b>Parameter</b>	<b>ingress-service-pool</b> : ingress shared service pool
<b>Description</b>	<b>egress-service-pool</b> : egress shared service pool <i>sp-id</i> : ID of shared pool <i>value</i> : percentage, range: 1-100
<b>Defaults</b>	The default value is 0, indicating that no alarm is reported.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ↘ Configuring the priority group/queue buffer utilization alarm threshold

- Optional.
- In the interface configuration mode, use the **mmu usage-warn-limit {pg-headroom | priority-group | unicast | multicast} [id1 [id2 [idN]] set value** command to configure the buffer utilization alarm threshold for each priority group or queue.
- Use the **no** or **default** command of this command to restore the default settings.

<b>Command</b>	<b>mmu usage-warn-limit { pg-headroom   priority-group   unicast   multicast } [id1 [id2 [idN]] set value</b>
<b>Parameter</b>	<b>priority-group</b> : priority group
<b>Description</b>	<b>pg-headroom</b> : priority group headroom <b>unicast</b> : performs buffer management on the egress unicast queue <b>multicast</b> : performs buffer management on the egress multicast queue <i>idN</i> : priority group/queue ID <i>value</i> : percentage, range: 1-100
<b>Defaults</b>	The default value is 0, indicating that no alarm is reported.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	N/A

#### ↘ Configuring the monitoring data sampling interval

- Optional.
- In global configuration mode, use the **mmu sample-period { buffer-counter | queue-counter } value** command to configure the monitoring data sampling interval for each queue.
- Use the **no** or **default** form of the command to restore the default setting.

<b>Command</b>	<b>mmu sample-period { buffer-counter   queue-counter } value</b>
<b>Parameter Description</b>	<b>buffer-counter</b> : count of occupied buffer <b>queue-counter</b> : count of sent and discarded records in a queue <b>value</b> : sampling interval in the unit of seconds, range: 1-10
<b>Defaults</b>	The sampling interval is 5 seconds by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### Verification

- Use the **show running-config** command to check whether the MMU under the corresponding interface is configured successfully.
- Use the **show queue-buffer** command to check whether the configuration succeeds.

#### ✚ Configuring the numbering mode of slice ID

- Optional.
- In global configuration mode, use the **mmu slice-id compatible** command to configure the numbering mode of slice ID and switch the numbering mode of CLI/MIB.
- Use the **no** or **default** form of the command to restore the default setting.

<b>Command</b>	<b>mmu slice-id compatible</b>
<b>Parameter Description</b>	
<b>Defaults</b>	By default, the number of slice ID starts from 1; run the command to start ID from 0.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### Verification

- Run the **show run** command to display the current numbering mode.
- Run the **show queue-buffer** command to display the range of current numbering mode.

#### Configuration Examples

##### ✚ Configuring the buffer utilization alarm limit based on port group

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● On the switch, configure the buffer utilization alarm threshold of port group as 80%.</li> </ul>
	<pre>FS# configure terminal</pre>

	<pre>FS(config)# mmu usage-warn-limit set 80 FS(config)#</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the buffer utilization alarm threshold has been configured successfully.</li> </ul>
	<pre>FS# show run running-config   include mmu mmu usage-warn-limit set 80</pre>

📌 **Configuring the buffer utilization alarm limit based on egress queue**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure the buffer utilization alarm threshold as 70% at the unicast queues 6 and 8 of port 1/1 on the switch.</li> </ul>
	<pre>FS# configure terminal FS(config)# int te1interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)#mmu usage-warn-limit unicast 6 8 set 70</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the buffer utilization alarm threshold has been configured successfully.</li> </ul>
	<pre>FS# configure terminal FS(config)# interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)#show this Building configuration... ! mmu usage-warn-limit unicast 6 set 70 mmu usage-warn-limit unicast 8 set 70 ! end FS(config-if-TFGigabitEthernet 0/1)# show queue-buffer interface TFGigabitEthernet 0/1 Interface TFGigabitEthernet 0/1: Slice 1: Type      Queue Used cells Available cells Usage Usage warn limit Usage warn count Peaked cells Service pool   Unicast  1      0      97849      0%      0%      0      0 0(SP-0)   Unicast  2      0      97849      0%      0%      0      0 0(SP-0)   Unicast  3      0      97849      0%      0%      0      0 0(SP-0)   Unicast  4      0      97849      0%      0%      0      0 0(SP-0)   Unicast  5      0      97849      0%      0%      0      0 0(SP-0)   Unicast  6      0      97849      0%      70%      0      0 0(SP-0)   Unicast  7      0      97849      0%      0%      0      0 0(SP-0)   Unicast  8      0      97849      0%      70%      0      0</pre>

### 3.4.3 Configuring the Queue Packet Loss Detection

#### Configuration Effect

- Enable/Disable the global queue packet loss alarm of all interface queues.
- Enable/Disable the queue packet loss alarm on an interface. The priority of this configuration is higher than the global configuration.
- Configure the packet loss alarm frequency so that only  $N$  packet loss alarms are displayed in the period of  $T$ .

#### Notes

- This function can be configured in global configuration mode and interface configuration mode.

#### Configuration Steps

##### ▾ Configuring the packet loss alarm

- Optional.
- In global or interface configuration mode, run the `mmu queue-loss-warn {unicast | multicast} [qid1 [qid2 [qidN]]] {on | off}` command to enable/disable the packet loss alarm function on queues.
- Use the `no` or `default` form of this command to restore default configuration. The packet loss alarm function is disabled by default.

<b>Command</b>	<b>[no] mmu queue-loss-warn {unicast   multicast } [qid1 [qid2 [qidN] ] ] {on   off}</b>
<b>Parameter Description</b>	Unicast: Indicates a unicast queue. <b>multicast</b> : Indicates a multicast queue. <i>qid</i> : Indicates the queue ID, range: 1-8. <b>on</b> : Enables the packet loss alarm. <b>off</b> : Disables the packet loss alarm.
<b>Defaults</b>	The packet loss alarm function is disabled by default.
<b>Command Mode</b>	Global configuration mode and interface configuration mode.
<b>Usage Guide</b>	The priority of interface configuration is higher than the global configuration.

↘ **Configuring the Packet Loss Alarm Frequency**

- Optional.
- In global configuration mode, run the **mmu queue-loss-warn frequency cycle value1 times value2** command to configure the packet loss alarm frequency.
- Use the **no** or **default** form of the command to restore the default configuration.

<b>Command</b>	<b>[no] mmu queue-loss-warn frequency cycle value1 times value2</b>
<b>Parameter Description</b>	<i>value1</i> : Indicates the displaying period of the packet loss alarm. <i>value2</i> : Indicates the number of packet loss alarms that can be displayed in a period.
<b>Defaults</b>	Up to 30 packet loss alarms can be displayed within 60s by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	

**Verification**

- Use the **show running-config** command to check whether the configuration takes effect.

**Configuration Examples**

↘ **Configuring the queue packet loss alarm**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the packet loss alarm for the unicast queue 5 in the global configuration mode.</li> <li>● Enable the packet loss alarm for the unicast queue 7 in the interface configuration mode.</li> </ul>
	<pre>FS# configure terminal FS(config)#mmu queue-loss-warn unicast 5 on FS(config)#interface TFGigabitEthernet 0/1 FS(config-if-TFGigabitEthernet 0/1)#mmu queue-loss-warn unicast 7 on</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the alarm is enabled.</li> </ul>
	<pre>FS# show running-config ... mmu queue-loss-warn unicast 5 on ...</pre>

```

FS#show running-config interface TFGigabitEthernet 0/1
Building configuration...
Current configuration : 68 bytes

interface TFGigabitEthernet 0/1
mmu queue-loss-warn unicast 7 on
FS#
    
```

↘ **Configuring the frequency of queue packet loss alarm**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure at most 100 alarm syslogs can be printed during 100s in the global configuration mode.</li> </ul>
	<pre> FS# configure terminal FS(config)# mmu queue-loss-warn frequency cycle 100 times 100 FS(config)#         </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the frequency is configured.</li> </ul>
	<pre> FS# show running-config   include mmu mmu queue-loss-warn frequency cycle 100 times 100         </pre>

**3.4.4 Configuring the Cut-through Mode**

**Configuration Effect**

- Enable the cut-through function to reduce the packet forwarding delay.

**Notes**

- The cut-through function can be configured only on physical ports.

**Configuration Steps**

↘ **Configuring cut-through mode**

- Optional.
- In interface configuration mode, run the **mmu cut-through** command to enable the cut-through function on the interface.
- Use the **no** or **default** form of the command to restore the default setting.

<b>Command</b>	<b>mmu cut-through</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The cut-through mode is disabled by default.
<b>Command Mode</b>	Interface configuration mode

<b>Usage Guide</b>	The mode can not take effect in the case of interface congestion.
--------------------	---

#### Verification

- Use the **show running-config** command to check whether the configuration takes effect.

#### Configuration Examples

##### ✚ Configuring the cut-through mode

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the cut-through mode in the global configuration mode.</li> </ul>
	<pre>FS# configure terminal FS(config)#mmu cut-through</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the cut-through mode is configured.</li> </ul>
	<pre>FS# show running-config   include mmu mmu cut-through</pre>

### 3.4.5 Configuring MMU-HA

#### Configuration Effect

- Disable the MMU-HA function
- Disable the MMU-HA reset function but keep the MMU buffer crash detection

#### Notes

- This function can be configured on the physical port in global configuration mode.

#### Configuration Steps

##### ✚ Disabling MMU-HA

- Optional.
- In global configuration mode, run the **mmu ha disable** command to disable the function.
- Use the **no** or **default** form of this command to restore default configuration.

<b>Command</b>	<b>mmu ha disable</b>
<b>Parameter Description</b>	
<b>Defaults</b>	The MMU-HA function is enabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	

##### ✚ Disabling MMU-HA reset function

- Optional
- In the global configuration mode, use the **mmu ha reset disable** command to disable MMU-HA reset function

- Use the no form of this command to restore the default settings

<b>Command</b>	<b>mmu ha reset disable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	MMU-HA reset is enabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### Verification

- Use the **show running-config** command to check whether the configuration takes effect.

#### Configuration Examples

##### ↘ Disabling MMU-HA function

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure in the global configuration mode.</li> </ul>
	<pre>FS# configure terminal FS(config)# mmu ha disable</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the configuration takes effect.</li> </ul>
	<pre>FS# show running-config mmu ha disable</pre>

##### ↘ Disabling MMU-HA reset function

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure in the global configuration mode.</li> </ul>
	<pre>FS# configure terminal FS(config)# mmu ha reset disable</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the configuration takes effect.</li> </ul>
	<pre>FS# show running-config   include mmu mmu ha reset disable</pre>

### 3.4.6 Configuring MMU-TCB

#### Configuration Effect

- Enable MMU-TCB to monitor the TCP/UDP packet loss of the unicast queue. When the packet loss occurs, the five-element tuple of packet will be collected and reported to the GRPC server.

#### Notes

- This function can be configured in global configuration mode.

## Configuration Steps

### ✚ Configuring the packet loss monitoring

- Optional.
- In global configuration mode, run the **mmu tcb-enable** command to enable/disable the packet loss monitoring function.
- Use the **no** or **default** form of this command to restore default configuration. The packet loss monitoring function is disabled by default.

<b>Command</b>	<b>[no] mmu tcb-enable</b>
<b>Parameter Description</b>	
<b>Defaults</b>	The packet loss monitoring function is disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Only devices using TD3/TH2 support this function. The monitoring data collected by TCB is reported to the server by GRPC.

### Verification

- Use the **show running-config** command to check whether the configuration takes effect.

### Configuration Examples

#### ✚ Enabling MMU-TCBfunction

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure in the global configuration mode.</li> </ul> <pre>FS# configure terminal FS(config)# mmu tcb-enable</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check whether the configuration takes effect.</li> </ul> <pre>FS# show running-config mmu tcb-enable</pre>

## 3.5 Monitoring

### Clearing

-  Running the **clear** command during operation of the equipment may lead to service interruption due to loss of important information.

Description	Command
Clears the queue counter value.	<b>clear queue-counter</b>
Clears the historical peak value of the egress queue buffer	<b>clear mmu queue-buffer peaked</b>
Clears the historical peak value of the	<b>clear mmu pg-buffer peaked</b>

ingress PG buffer	
Clears the number of times that the occupied buffer exceeds the warning threshold	<b>clear mmu usage-warn-count</b>

### Displaying

Description	Command
Displays the buffer use information of panel interface.	<b>show queue-buffer interface</b>
Displays the queue counter information of panel interface.	<b>show queue-counter interface</b>
Displays the buffer use information of the ingress PG	<b>show pg-buffer interface</b>

# 1 Configuring REUP

## 1.1 Overview

The Rapid Ethernet Uplink Protection Protocol (REUP) provides a rapid uplink protection function.

In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.

The upstream interfaces of REUP are configured in pairs. If both interfaces are normal, an interface works in the backup state. The interface in the backup state does not forward data packets. When the interface in the forward state is faulty, the backup interface switches to the forward state immediately, and provides data transmission. In addition, REUP also sends address update packets to upstream devices so that the upstream devices can update their MAC addresses immediately. This function of REUP ensures that layer-2 data streams can be restored within 50 ms after a link is faulty.

REUP is mutually exclusive with the Spanning Tree Protocol (STP) based on interfaces. In this case, a device runs STP downward and runs REUP upward to implement backup and fault protection for the upstream link. REUP ensures that basic link redundancy is provided when STP is disabled and that millisecond-level fault recovery faster than STP is also provided.

### Protocols and Standards

- REUP is a proprietary protocol of FS Network, and there is no standard and protocol for reference.

## 1.2 Applications

Application	Description
<a href="#">Communication in Dual Uplink Networking</a>	Forward packets in the dual-uplink networking.

### 1.2.1 Communication in Dual Uplink Networking

#### Scenario

For communication in dual uplink networking, the access switch has two uplink paths, as shown in Figure 1-1.

Figure 1-1 Dual uplink networking

**Deployment**

- Enable REUP on interface1 and interface2 of the access switch D/E to implement fast switching when a link is faulty.
- Enable MAC address update message receiving of REUP on the interfaces connected to switches A/B/C to rapidly clear the MAC addresses on the interfaces when a link is faulty.

**1.3 Features**

**Basic Concepts**

▾ **REUP Pair**

Specify an interface as the backup interface of another interface to configure an REUP pair. One interface is the active interface and the other interface is the backup interface. When the two interfaces are normal, an interface is configured as the forward interface whereas the other interface is configured as the backup interface. You can determine the interface to be configured as the backup interface. See the related information in the section "Configuring the Preemption Mode and Delay Time of REUP".

▾ **MAC Address Update Message**

MAC address update messages refer to FLUSH packets sent by FS Network to uplink devices through private multicast. When an uplink device of FS Network enables the function for receiving MAC address update messages and receives MAC address update messages, the device updates the MAC addresses of corresponding interfaces.

### ↘ **MAC Address Update Group**

Multiple interfaces are added to a group. If one interface in the group receives a MAC address update message, the MAC addresses of other interfaces in the group will be updated. In this case, the group is called MAC address update group.

### ↘ **MAC Address Update Packet**

Packets sent to update MAC addresses in order to support uplink devices are called MAC address update packets.

### ↘ **Link Tracking Group**

The uplink and downstream interfaces of a device are added to a group. If all upstream interfaces in the group are down, all downstream interfaces in this group are forced down. In this case, this group is called a link tracing group.

## Overview

Feature	Description
<a href="#">Dual Link Backup of REUP</a>	When a link is faulty, the other link can rapidly switch to the forward state.
<a href="#">Preemption Mode and Delay Time of REUP</a>	When both links are normal, the preemption mode can be used to determine the link that is used for forwarding data and the delay time that is used to determine the waiting time before switching.
<a href="#">MAC Address Update</a>	During link switching, the MAC address of an interface is updated to make packet convergence faster.
<a href="#">VLAN Load Balance</a>	When the two links are normal, the utilization of link bandwidth can be maximized.
<a href="#">Link State Tracking</a>	When the upstream link is faulty, the downstream link is switched.

### 1.3.1 Dual Link Backup of REUP

When an active link is faulty, the link in the backup state will rapidly switch to the forward state and start forwarding data, minimizing the service interruption caused by link failure.

#### Working Principle

Specify an interface as the backup interface of another interface to configure an REUP pair. When the two interfaces are normal, a link is in the forward state (forwarding data packets) and the other link is in the backup state (not forwarding data). When the active link is faulty, the link in the backup state rapidly switches to the forward state and starts forwarding data. When the faulty link is recovered, the link enters the backup state and does not forward data packets. Of course, you can configure the preemption mode to specify whether a link recovered from failure preempts the link that is in the forward state currently.

Figure 1-2 A topology with two normal links

As shown in Figure 1-2, connect interfaces 1 and 2 of switch D (E) to the uplink switches B and C (C and B) and configure REUP on interfaces 1 and 2. When the links are normal, interface 1 is in the forward state and forwards data packets and interface 2 is in the backup state and does not forward data packets.

Figure 1-3 A topology with interface 1 of switch D (E) faulty

Once interface 1 is faulty, interface 2 immediately starts forwarding data packets and recovers the uplink transmission of the switch. In the non-preemption mode, when the link of interface 1 is recovered, interface 1 is in the backup state and does not forward data packets whereas interface 2 continues forwarding data packets.

## Related Configuration

### 📌 Enabling Dual Link Backup on an interface

By default, dual link backup on an interface is disabled.

You can run the **switchport backup interface** command to configure a layer-2 physical interface (or layer-2 AP interface) as a backup interface and enable the dual link backup function of REUP.

You must enable the dual link backup function of REUP on an interface. The function involves the link switching of REUP only when an interface is faulty.

- ❗ REUP, ERPS, and RERP do not share interfaces.
- ❗ Devices enabled with REUP must disable the storm control function of all layer-2 interfaces.

## 1.3.2 Preemption Mode and Delay Time of REUP

### Working Principle

You can determine which link should be used first by configuring the preemption mode of REUP. If the preemption mode is set to bandwidth first, REUP selects a link with a high bandwidth first. You can also set the preemption mode to forced to select a stable and reliable link first forcibly.

To avoid frequent active/backup link switching caused by abnormal faults, REUP provides a preemption delay function. When the two links are recovered, link switching is performed when the faulty link becomes stable after a delay (35s by default).

## Related Configuration

### ↳ Configuring the Preemption Mode and Delay Time of REUP

By default, the preemption mode is disabled and the delay time is 35s.

You can run the **switchport backup interface preemption mode** command to configure the preemption mode.

You can run the **switchport backup interface preemption delay** command to configure the delay time.

A smaller delay means more frequent preemption switching after the faulty link is recovered.

-  REUP uses the value of the **Bandwidth** attribute for an AP interface as the actual bandwidth of the AP interface, which is equal to the value of the **Speed** attribute (the number of link up member interfaces x the number of member interfaces).
-  When an uplink enables STP, the preemption delay time of REUP is greater than 35s.

### 1.3.3 MAC Address Update

During link switching, the MAC address of an interface is updated to make packet convergence faster.

#### Working Principle

As shown in Figure 1-2, interface 1 and interface 2 of switch D (E) are enabled with dual link backup of REUP. Interface 1 works as the active interface. During normal communication, switch A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the interfaces connecting to switch B (C).

When interface 1 of switch D (E) is faulty, interface 2 rapidly switches to the forward state and starts forwarding data packets. In this case, switch A does not learn the MAC addresses of users 1 and 2 (users 3 and 4) on the interfaces connecting to switch B (C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to switch C (B) by switch A, causing that the packets from the server to users 1 and 2 (users 3 and 4) are lost.

To avoid the preceding problems, you can enable the MAC address update function on switch D (E). When interface 2 starts forwarding packets, switch D (E) sends a MAC address update message to interface 2. After receiving the MAC address update message, switch A updates the MAC address on the interface of switch A. In this way, switch A forwards the packets sent by the server to the users to the interfaces of switch B (C) to make packet convergence faster.

In addition, import the setting of a MAC address update group, that is, classify multiple interfaces into the same group. When an interface in this group receives a MAC address update message, the MAC addresses on other interfaces in the group are updated to reduce the side effect of flooding caused by MAC address update.

To be compatible with upstream devices not supporting MAC address update messages, switch D (E) will send MAC address update packets for users 1 and 2 (users 3 and 4) upward when interface 2

switches to the forward state. In this way, switch A can update the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding interfaces and recover the downlink data transmission of switch A.

## Related Configuration

### ✎ Enabling Sending of MAC Address Update Messages on an interface

By default, sending of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update transit** command to enable sending of MAC address updates on all interfaces of a device.

If sending of MAC address update messages is not enabled, MAC address update messages will not be sent when dual link backup switching of REUP is performed.

### ✎ Enabling Receiving of MAC Address Update Messages on an interface

By default, receiving of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update receive** command to enable receiving of MAC address updates on all interfaces of a device.

If receiving of MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during dual link backup switching of REUP and will not update the MAC addresses.

### ✎ Configuring a VLAN for Sending MAC Address Update Messages

By default, a VLAN for sending MAC address update messages is the default VLAN to which an interface belongs.

You can run the **mac-address-table move update transit vlan** command to configure the VLAN in which interfaces send MAC address update messages.

If the VLAN in which interfaces send MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.

### ✎ Configuring a VLAN for Receiving MAC Address Update Messages

By default, MAC address update messages are received in all VLANs.

You can run the **no mac-address-table move update receive vlan** command to configure a VLAN in which interfaces do not receive MAC address update messages. MAC address update messages are received in remaining VLANs.

If no VLAN in which interfaces receive MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the remaining VLANs.

### ✎ Configuring a MAC Address Update Group

By default, there is no MAC address update group.

You can run the **mac-address-table update group** command to add an interface to the MAC address update group. The interface is added to the first update group by default.

If no MAC address update group is configured, MAC address update will not be performed when MAC address update packets are received.

#### ↘ **Configuring the Maximum Number of MAC Address Update Packets Sent Per Second**

By default, the maximum number of MAC address update packets sent per second is 150.

You can run the **mac-address-table move update max-update-rate** command to configure the maximum number of MAC address update packets sent per second.

The larger the number of packets, the more CPU time used for sending the packets, and the fewer downlink packets are lost.

### **1.3.4 VLAN Load Balance**

#### **Working Principle**

The VLAN load balance function allows REUP to forward data packets of mutually exclusive VLANs for two interfaces to make full use of the link bandwidth.

As shown in Figure 1-4, configure dual link backup of REUP and enable VLAN load balance of REUP on interface 1 and interface 2 of switch D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through interface 1 and all the other data of VLAN 2 (instance 2) is transmitted through interface 2. Perform the same processing on switch E.

When an interface is faulty, the other interface takes over the transmission of all VLANs. When the faulty interface is recovered and does not become faulty within the preemption delay, the transmission of VLANs is switched back to the recovered interface.

Figure 1-4 A topology with two normal links of load balance

**Related Configuration**

📌 **Enabling VLAN Load Balance on an interface**

By default, the VLAN load balance function on an interface is disabled.

You can run the **switchport backup interface prefer instance** command to enable the VLAN load balance function.

If this function is not enabled, the link bandwidth cannot be fully used when packets are forwarded when the two links are normal. You must enable the VLAN load balance function on a port so that the interface can be involved in VLAN load balance.

**i** The instance mapping of REUP VLAN load balance is controlled by the MSTP module in a unified manner. For details about how to configure the instances, see the description in the *Configuring MSTP*.

**!** The VLAN load balance function can be configured only on trunk, uplink or hybrid interfaces.

**1.3.5 Link State Tracking**

Link tracking means that when the upstream link is faulty, services are switched to the downstream link so that the backup interface can continue forwarding packets.

**Working Principle**

Link state tracking provides the function of notifying downlink devices for link switching when the upstream link is faulty. You can configure the uplink and downstream interfaces of a link state tracking group and bind the link status of multiple downstream interfaces to the interfaces of multiple upstream links to implement link status synchronization. When all upstream links in a tracking group are faulty, the interfaces of the downstream links are shut down forcibly to ensure that the transmission of the downstream links is switched from the active link to the backup link.

As shown in Figure 1-5, when the upstream link of switch B is faulty, link state tracking rapidly shuts down the downstream interface of switch B so that the uplink transmission of switch D is switched to switch C.

Figure 1-5 A topology where the upstream link of the active link is faulty

## Related Configuration

### ▾ Enabling Link Tracking

Link tracking is disabled by default.

You can run the **link state track** *[number]* command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1).

If link tracking is not enabled, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

### ▾ Enabling the Downlink Delay Up Function for a Link Tracking Group

By default, the downlink delay for link tracking is 0s.

You can run the **link state track number up-delay timer** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1). The value of **timer** ranges from 0 to 300s, which is 0s by default.

By enabling the downlink delay up function, you can avoid frequent downlink switching caused by uplink flapping in a link tracking group. That is, when the upstream link becomes up, the downstream link becomes up after a delay.

#### ➤ Adding an interface to a Link Tracking Group

By default, an interface is not added to a link tracking group.

You can run the **link state group [number] {upstream | downstream}** command to set upstream interfaces and downstream interfaces of the link tracking group. The value of **number** ranges from 1 to 2. An interface is added to the first link tracking group by default (the default value of **number** is 1).

If an interface is not added to a tracking group, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

## 1.4 Configuration

Configuration	Description and Command	
<a href="#">Configuring Basic Functions of REUP</a>	 (Mandatory) It is used to enable dual link backup of REUP.	
	<b>switchport backup interface</b>	Enables dual link backup of REUP.
<a href="#">Configuring the Preemption Mode and Delay Function of REUP</a>	 (Optional) It is used to determine the preemption mode and delay time. The default values are used if they are not configured.	
	<b>switchport backup interface preemption mode</b>	Sets the preemption mode.
	<b>switchport backup interface preemption delay</b>	Sets the delay time for preemption.
<a href="#">Configuring MAC Address Update</a>	 (Optional) It is used to enable rapid update of MAC addresses.	
	<b>mac-address-table update group</b>	Sets the MAC address update group ID of a switch.
	<b>mac-address-table move update transit</b>	Enables sending of MAC address update messages.
	<b>mac-address-table move update transit vlan</b>	Enables sending of the VLAN ID of MAC address update messages.
	<b>mac-address-table move update</b>	Configures the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
	<b>mac-address-table move update receive</b>	Enables receiving of MAC address update messages.
	<b>mac-address-table move update receive vlan</b>	Configures the VLAN range for processing MAC address update messages.
<a href="#">Configuring VLAN Load Balance</a>	 (Optional) It is used to enable VLAN load balance.	

Configuration	Description and Command	
	<b>switchport backup interface prefer instance</b>	Configures the link VLAN load balance of REUP.
<u>Configuring Link Tracking</u>	 (Optional) It is used to enable link tracking.	
	<b>link state track up-delay</b>	Enables the downlink delay up for a link state tracking group.
	<b>link state track</b>	Enables a link state tracking group.
	<b>link state group</b>	Add an interface as an upstream interface or a downstream interface of a specified link state tracking group.

### 1.4.1 Configuring Basic Functions of REUP

#### Configuration Effect

- When a link is faulty, the other normal link is switched to the forward state immediately for forwarding packets.

#### Notes

- An interface belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different interfaces.
- REUP supports layer-2 physical interfaces and AP interfaces, but does not support AP member interfaces.
- The active and backup interfaces may be of different types and have different rates. For example, an AP interface can be used as the active interface whereas a physical interface is configured as the backup interface.
- Interfaces configured with REUP are not involved in STP calculation.
- Each device can be configured with a maximum of 16 REUP pairs.
- Interfaces successfully configured with REUP cannot change interfaces to layer-3 interfaces or be added to an AP.

#### Configuration Steps

##### ▾ Enabling Dual Link Backup of REUP

- Mandatory.
- If there is no special requirement, dual link backup of REUP should be enabled on an interface of the receiving switch.

#### Verification

Run the **show interfaces switchport backup [detail]** command to check whether dual link backup of REUP is configured.

#### Related Commands

##### ▾ Enabling Dual Link Backup of REUP

<b>Command</b>	<b>switchport backup interface</b> <i>interface-id</i>
<b>Parameter</b>	<i>interface-id</i> : Indicates the backup interface ID.
<b>Description</b>	
<b>Command Mode</b>	Interface configuration mode

<b>Usage Guide</b>	If the interface where the mode resides is the active interface, the interface corresponding to the <b>interface-id</b> parameter is the backup interface. When the active link is faulty, rapidly recover the transmission of the backup link.
--------------------	---

### Configuration Example

#### ▾ Enabling Dual Link Backup of REUP

<p><b>Scenario</b></p> <p><b>Figure 1-6</b></p> <p><b>Dual uplink networking</b></p>	<p>As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D &gt; switch B &gt; switch A and switch D &gt; switch C &gt; switch A. There are two upstream links from switch E to switch A, which are switch E &gt; switch B &gt; switch A and switch E &gt; switch C &gt; switch A.</p> 
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>Configure dual link backup (the interface Gi0/1 is the active interface and Gi0/2 is the backup interface) of REUP on the access switch D (E).</li> </ul>
<p><b>D</b></p>	<pre>SwitchD&gt; enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
<p><b>E</b></p>	<pre>SwitchE&gt; enable SwitchE# configure terminal SwitchE(config)# interface GigabitEthernet 0/1 SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchE(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>

<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check the dual link backup information configured for switch D (E).</li> </ul>
<b>D</b>	<pre>SwitchD#show interfaces switchport backup detail  Switch Backup Interface Pairs:  ActiveInterface      BackupInterface      State ----- Gi0/1                Gi0/2                Active Up/Backup Standby  Interface Pair : Gi0/1, Gi0/2  Preemption Mode : off  Preemption Delay : 35 seconds  Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>
<b>E</b>	<pre>SwitchE#show interfaces switchport backup detail  Switch Backup Interface Pairs:  ActiveInterface      BackupInterface      State ----- Gi0/1                Gi0/2                Active Up/Backup Standby  Interface Pair : Gi0/1, Gi0/2  Preemption Mode : off  Preemption Delay : 35 seconds  Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>

**Common Errors**

- Other REUP pairs are configured on a configured interface.
- A configured interface is not a layer-2 physical interface or AP interface.

**1.4.2 Configuring the Preemption Mode and Delay Function of REUP**

**Configuration Effect**

- Restrict the preemption mode and preemption delay time for REUP link switching.

**Notes**

- Dual link backup of REUP must be configured.

**Configuration Steps**

- Optional.

- If the active link needs to always forward packets or the link bandwidth needs to be used to determine the link for forwarding packets, the corresponding preemption mode and delay time must be configured.

### Verification

Run the **show interfaces switchport backup [detail]** command to check whether the preemption mode and delay time are consistent with the configurations.

### Related Commands

#### ▾ Configuring the Preemption Mode of REUP

<b>Command</b>	<b>switchport backup interface <i>interface-id</i> preemption mode {forced bandwidth off}</b>
<b>Parameter</b>	<i>interface-id</i> : Indicates the backup interface ID.
<b>Description</b>	<b>mode</b> : Sets the preemption mode: <b>forced</b> : Indicates the forced mode. <b>bandwidth</b> : Indicates the bandwidth mode. <b>off</b> : Indicates that the preemption mode is off.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The preemption modes include forced, bandwidth and off. In the bandwidth mode, an interface with a high bandwidth is selected first to transmit data; in the forced mode, the active interface is selected first to transmit data; in the off mode, no preemption is performed. The default mode is off.

#### ▾ Configuring the Delay Time of REUP

<b>Command</b>	<b>switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i></b>
<b>Parameter</b>	<i>interface-id</i> : Indicates the backup interface ID.
<b>Description</b>	<i>delay-time</i> : Indicates the delay time.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Preemption delay indicates the delay time after a faulty link is recovered to the time when link switching is performed again.

### Configuration Example

#### ▾ Configuring the Preemption Mode and Delay Time of REUP

<b>Scenario</b>	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure the preemption mode to bandwidth on the access switch D (E) and the delay time to 40s.</li> </ul>
<b>D</b>	<pre>SwitchD&gt; enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth</pre>

	<pre>SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preempton delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
<b>E</b>	<pre>SwitchE&gt; enable SwitchE# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preempton mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preempton delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check the dual link backup information configured for switch D (E).</li> </ul>

**Common Errors**

- A configured interface is not a layer-2 physical interface or AP interface.

### 1.4.3 Configuring MAC Address Update

#### Configuration Effect

- Rapidly delete and update MAC addresses of an interface during link switching to make packet convergence faster.

#### Notes

- Dual link backup of REUP must be configured.
- Each device can be configured with a maximum of 8 address update groups. Each address update group can have a maximum of 8 member interfaces and an interface can belong to multiple address update groups.

#### Configuration Steps

- Mandatory.
- If there is no special requirement, the MAC address update function should be configured.

#### Verification

Run the **show mac-address-table update group [detail]** command to view the update group configuration.

#### Related Commands

##### ▾ Configuring the MAC Address Update Group ID of a Switch

<b>Command</b>	<b>mac-address-table update group [group-num]</b>
<b>Parameter Description</b>	<i>group-num</i> : Indicates the MAC address update group ID.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	In order to reduce large flooding caused by MAC address update which may affect normal data transmission of the switch, we add a setting of a MAC address update group. Only after all interfaces on a switching path are added to the same MAC address update group, transmission of downlink data can be rapidly recovered.

##### ▾ Enabling Sending of MAC Address Update Messages

<b>Command</b>	<b>mac-address-table move update transit</b>
<b>Parameter Description</b>	-
<b>Command Mode</b>	Command Mode
<b>Usage Guide</b>	To reduce link switching and loss of downlink data streams, you need to enable sending of MAC address update messages on a switch that performs switching.

##### ▾ Enabling Sending of the VLAN ID of MAC Address Update Messages

<b>Command</b>	<b>mac-address-table move update transit vlan vid</b>
<b>Parameter</b>	<i>vid</i> : Indicates the VLAN ID for sending MAC address update messages.

<b>Description</b>	
<b>Command</b>	Interface configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	After sending of MAC address update messages is enabled, MAC address update messages can be sent to uplink devices during link switching.

Configure the maximum number of MAC address update packets sent per second.

#### ▾ Configuring the Maximum Number of MAC Address Update Packets Sent Per Second

<b>Command</b>	<b>mac-address-table move update max-update-rate</b> <i>pkts-per-second</i>
<b>Parameter Description</b>	<i>pkts-per-second</i> : Indicates the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
<b>Command Mode</b>	Configuration mode
<b>Usage Guide</b>	During link switching, REUP sends MAC address update packets of a specified quantity to uplink devices per second to recover the downlink data transmission of the uplink device.

#### ▾ Enabling Receiving of MAC Address Update Messages

<b>Command</b>	<b>mac-address-table move update receive</b>
<b>Parameter Description</b>	-
<b>Command Mode</b>	Configuration mode
<b>Usage Guide</b>	During switching of dual link backup, downlink data streams may be lost since the MAC address table of the uplink switch is not updated in real time. In order to reduce loss of layer-2 data streams, you need to update the MAC address table of the uplink switch. In this case, you need to enable receiving of MAC address update messages on the uplink switch.

#### ▾ Configuring the VLAN Range for Processing MAC Address Update Messages

<b>Command</b>	<b>mac-address-table move update receive vlan</b> <i>vlan-range</i>
<b>Parameter Description</b>	<i>vlan-range</i> : Indicates the VLAN range for processing MAC address update messages.
<b>Command Mode</b>	Configuration mode
<b>Usage Guide</b>	This command is used to disable the function for processing MAC address update messages on certain VLANs. For a VLAN disabled with the function for processing MAC address update messages, MAC address update packets can be used to recover the downlink transmission of uplink devices; however, the convergence performance for link faults will be decreased.

### Configuration Example

#### ▾ Configuring MAC Address Update

<b>Scenario</b>	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
-----------------	---

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable sending of MAC address update messages on the access switch D (E).</li> <li>● Enable receiving of MAC address update packets on switch B (C).</li> <li>● Add all interfaces on the REUP switching path to the same MAC address update group.</li> <li>● In the environment, Gi0/1 and Gi0/3 of switch B are the interfaces on the switching path of switch D's uplink, and Gi0/3 and Gi0/2 are the interfaces on the switching path of switch E's uplink. You can add interfaces Gi0/1, Gi0/2 and Gi0/3 to the same address update group. Similarly, you can obtain the configuration of switch C.</li> <li>● Enable receiving of MAC address update packets on switch A.</li> <li>● Add all interfaces on the REUP switching path of switch A to the same MAC address update group.</li> </ul>

Gi0/2	0	0000.0000.0000	

**Common Errors**

- A configured interface is not a layer-2 physical interface or AP interface.

**1.4.4 Configuring VLAN Load Balance**

**Configuration Effect**

- Maximize the utilization of link bandwidth.

**Notes**

- Dual link backup of REUP must be configured.
- The Access interface cannot be shared by VLAN load balance and STP.
- For interfaces successfully configured with VLAN load balance, you cannot modify the attributes of the interfaces but can modify the VLAN attributes of the interfaces.

**Configuration Steps**

- If maximizing bandwidth utilization is not required, this configuration is optional.
- If there is a requirement for VLAN load balance, corresponding configuration must be performed.

**Verification**

Run the **show interfaces switchport backup [detail]** command to check whether VLAN load balance is configured.

**Related Commands**

▾ **Configuring VLAN Load Balance**

<b>Command</b>	<b>switchport backup interface <i>interface-id</i> prefer instance <i>instance-range</i></b>
<b>Parameter</b>	<i>interface-id</i> : Indicates the backup interface ID.
<b>Description</b>	<i>instance-range</i> : Indicates the load instance range of the backup interface.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.

**Configuration Example**

▾ **Configuring VLAN Load Balance**

<b>Scenario</b>	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. ### Common Errors

- The mappings between VLAN IDs and instances are not configured.

### 1.4.5 Configuring Link Tracking

#### Configuration Effect

- After detecting that the upstream link is disconnected, forcibly disconnect the downstream link so that link switching can be performed.

#### Notes

- Dual link backup of REUP must be configured.
- For the link state tracking function, each interface belongs to only one link state tracking group and each device can be configured with up to 2 link state tracking groups. Each link state tracking group can have 8 upstream interfaces and 256 downstream interfaces.

#### Configuration Steps

- Mandatory.
- If there is no special requirement, the uplink tracking function should be configured.

#### Verification

Run the **show link state group** command to view the configured link tracking information.

## Related Commands

## 2 Configuring RLDP

### 2.1 Overview

The Rapid Link Detection Protocol (RLDP) achieves rapid detection of unidirectional link failures, directional forwarding failures and downlink loop failures of an Ethernet. When a failure is found, relevant ports will be closed automatically according to failure treatment configuration or the user will be notified to manually close the ports to avoid wrong flow forwarding or an Ethernet layer-2 loop.

### 2.2 Applications

Application	Description
<u>Unidirectional Link Detection</u>	Detect a unidirectional link failure.
<u>Bidirectional Forwarding Detection</u>	Detect a bidirectional link failure.
<u>Downlink Loop Detection</u>	Detect a link loop.

### 2.2.1 Unidirectional Link Detection

#### Scenario

As shown in the following figure, A is connected to B via optical fiber. The two lines are the Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If any of the Tx of Port A, Rx of Port B, Tx of Port B and Rx of Port A fails, a unidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-1

<b>Remarks</b>	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.
----------------	--

#### Deployment

- Global RLDP is enabled.
- Configure unidirectional link detection under Port A and Port B and define a method for failure treatment.

### 2.2.2 Bidirectional Forwarding Detection

#### Scenario

As shown in the following figure, A is connected to B via optical fiber, and the two lines are Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If the Tx of Port A, Rx of Port B, Rx of Port A and Tx of Port B all fail, a bidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure2-2

<b>Remarks</b>	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.
----------------	--

#### Deployment

- Global RLDP is enabled.
- Configure BFD under Port A and Port B and define a method for failure treatment.

### 2.2.3 Downlink Loop Detection

#### Scenario

As shown in the following figure, A, B and C are connect into a loop. Downlink loop detection is enabled on A, and a loop is detected and treated.

Figure 2-3

<b>Remarks</b>	<p>A, B and C are layer-2 or layer-3 switches.</p> <p>A, B and C are interconnected via exchange ports.</p>
----------------	---

#### Deployment

- Global RLDP is enabled on A.
- Configure downlink loop detection on the Gi 2/0/1 and Gi 2/0/9 ports of A, and define a method for failure treatment.

### 2.3 Features

Most Ethernet link detection mechanisms detect link connectivity through automatic physical-layer negotiation. However, in some cases devices are connected on the physical layer and operate normally but layer-2 link communication is disabled or abnormal. The RLDP recognizes a neighbor device and detects a link failure through exchanging Prob packets, Echo packets or Loop packets with the device.

#### Basic Concepts

##### ↘ Unidirectional Link Failure

A unidirectional link failure occurs in case of a cross-connected optical fiber, a disconnected optical fiber, an open-circuit optical fiber, one open-circuit line in a twisted-pair cable, or unidirectional open circuit of an intermediate device between two devices. In such cases, one end of a link is connected and the other disconnected so that flow is forwarded wrongly or a loop guard protocol (for example, the STP) fails.

##### ↘ Bidirectional Link Failure

A bidirectional link failure occurs in case of two optical fibers, two open-circuit lines in a twisted-pair cable, or bidirectional open circuit of an intermediate device between two devices. In such cases, the both ends of a link are disconnected so that flow is forwarded wrongly.

#### ↘ Loop Failure

A downlink device is wrongly connected to form a loop, resulting in a broadcast storm.

#### ↘ RLDP Packet

The RLDP defines three types of packets: Prob packets, Echo packets and Loop packets.

- Prob packets are layer-2 multicast packets for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Echo packets are layer-2 unicast packets as response to Prob packets and used for unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Loop packets are layer-2 multicast packets for downlink loop detection. They can only be received. The default encapsulation format is SNAP.

#### ↘ RLDP Detection Interval and Maximum Detection Times

A detection interval and the maximum detection times can be configured for the RLDP. A detection interval determines the period of sending Prob packets and Loop packets. When a device receives a Prob packet, it replies with an Echo packet immediately. A detection interval and the maximum detection times determine the maximum detection time (equal to a detection interval × the maximum detection times + 1) for unidirectional or bidirectional link detection. If neither Prob nor Echo packet from a neighbor can be received within the maximum detection time, the treatment of unidirectional or bidirectional failure will be triggered.

#### ↘ RLDP Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer-end device as its neighbor. One port may learn one neighbor, which is variable. If negotiation is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation, which succeeds when a port receives a Prob packet from the neighbor. However, if the RLDP is enabled under a failure, the port cannot learn a neighbor so that detection cannot start. In this case, recover the link state before enabling the RLDP.

#### ↘ Treatment for Failed Port under RLDP

- Warning: Only print Syslog to indicate a failed port and a failure type.
- Shutdown SVI: Print Syslog, and then inquire an SVI according to the Access VLAN or Native VLAN of a port and shut down the SVI if the port is a physical exchange port or layer-2 AP member port.
- Port violation: Print Syslog, and configure a failed port as in violation state, and the port will enter Linkdown state physically.
- Block: Print Syslog, and configure the forward state of a port as Block, and the port will not forward packets.
- Monitor: Print Syslog, and monitor the port state in real time, and notify other modules of the port state.

### ↘ Recovery of Failed Port under RLDP

- Manual reset: Manually reset all failed ports to initialized state and restart link detection.
- Manual or automatic errdisable recovery: Recover all failed ports to initialized state manually or regularly (30s by default and configurable) and restart link detection.
- Automatic recovery: Under unidirectional or bidirectional link detection, if the treatment for failed ports is not specified as port violation, recover ports to initialized state based on Prob packets and restart link detection.
- Automatic **rdperror-recoverinterval**: Enable the device to recover all failed ports to initialized state regularly (Configurable) and restart link detection.

### ↘ Port State under RLDP

- normal: Indicates the state of a port after link detection is enabled.
- error: Indicates the state of a port after a unidirectional or bidirectional link failure or a loop failure is detected.

### ↘ Overview

Feature	Description
<a href="#">Deploying RLDP Detection</a>	Enable unidirectional or bidirectional link detection or downlink loop detection for failures and implement treatment.

#### 2.3.1 Deploying RLDP Detection

The RLDP provides unidirectional link detection, bidirectional forwarding detection and downlink loop detection.

#### Working Principle

##### ↘ Unidirectional Link Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives Prob packets but no Echo packets, or none of them, treatment for a unidirectional failure will be triggered and detection will stop.

##### ↘ Bidirectional Forwarding Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives neither Prob packets nor Echo packets from a neighbor, treatment for a bidirectional failure will be triggered and detection will stop.

##### ↘ Downlink Loop Detection

When this function is enabled, a port sends Loop packets regularly. In the following cases, a loop failure will be triggered after the same port or a different port receives the packets: in one case, the egress and ingress ports are the same routed port or layer-3 AP member port; in another case, the egress and ingress ports are exchange ports or layer-2 AP member ports in a same default VLAN and in Forward state. Treatment for the failure will be implemented and detection will stop.

## Related Configuration

- Configuring RLDP Detection

By default, RLDP detection is disabled.

You may run the global command **rldp enable** or the interface command **rldp port** to enable RLDP detection and specify a detection type and treatment.

You may run the **rldp neighbor-negotiation** command to neighbor negotiation, the **rldp detect-interval** to specify a detection interval, the **rldp detect-max** to specify detection times, the **rldp error-recover interval** to recover failed ports regularly, or the **rldp reset** to recover a failed port.

## 2.4 Configuration

Configuration	Description and Command
<a href="#">Configuring Basic RLDP Functions</a>	 (Mandatory) It is used to enable RLDP detection under global configuration mode.
	<b>rldp enable</b> Enables global RLDP detection on all ports.
	 (Mandatory) It is used to specify under interface configuration mode a detection type and failure treatment for an interface.
	<b>rldp port</b> Enables RLDP detection on a port and specifies a detection type and failure treatment.
	 (Optional) It is used to configure a detection interval, detection times and neighbor negotiation under global configuration mode.
	<b>rldp detect-interval</b>
	<b>rldp detect-max</b>
	<b>rldp neighbor-negotiation</b>
	<b>rldp error-recover interval</b> Configures the time interval for recovering failed ports. This function is disabled by default.
	 (Optional) It is used under privileged mode.
<b>rldp reset</b> Recovers all ports.	

### 2.4.1 Configuring Basic RLDP Functions

#### Configuration Effect

- Enable RLDP unidirectional link detection, bidirectional forwarding detection, or downlink loop detection to discover failures.

#### Notes

- Loop detection is effective to all member ports of an AP when configured on one of the ports. Unidirectional link detection and bidirectional forwarding detection are effective only on an AP member port.
- The loop detection on a physical port added to an AP shall be configured the same as that of the other member ports. There are three cases. First, if loop detection is not configured on a newly-added port but on the existing member ports, the new port

adopts the configuration and detection results of the existing ports. Second, if a newly-added port and the existing member ports have different loop detection configuration, the new port adopts the configuration and detection results of the existing ports.

- When configuring the RLDP on an AP port, you may configure failure treatment only as "shutdown-port", to which other configurations will be modified.
- When "shutdown-port" is configured on a port, RLDP detection cannot be restored in case of a failure. After troubleshooting, you may run the **rldpreset** or **errdisable recovery** command to restore the port and resume detection. For configuration of the **errdisable recovery** command, please refer to the *SWITCH-INTF-SCG.doc*.

## Configuration Steps

### ↘ Enabling RLDP

- Mandatory.
- Enable RLDP detection on all ports under global configuration mode.

### ↘ Enabling Neighbor Negotiation

- Optional.
- Enable the function under global configuration mode, and port detection will be started under successful neighbor negotiation.

### ↘ Configuring Detection Interval

- Optional.
- Specify a detection interval under global configuration mode.

### ↘ Configuring Maximum Detection Times

- Optional.
- Specify the maximum detection times under global configuration mode.

### ↘ Configuring a Time Interval for Recovering Failed Ports

- Optional.
- Configure the time interval for recovering the failed port under global configuration mode.

### ↘ Configuring Detection under Port

- Mandatory.
- Configure unidirectional RLDP detection, bidirectional RLDP detection or downlink loop detection under interface configuration mode, and specify failure treatment.

### ↘ Restoring All Failed Ports

- Optional.
- Enable this function under privileged mode to restore all failed ports and resume detection.

## Verification

- Display the information of global RLDP, port and neighbor.

## Related Commands

### ✚ Modifying Global RLDP Detection Parameters

<b>Command</b>	<code>rldp { detect-interval <i>interval</i>   detect-max <i>num</i>   neighbor-negotiation }</code>
<b>Parameter Description</b>	<b>detect-interval <i>interval</i></b> : Indicates a detection interval. <b>detect-max <i>num</i></b> : Indicates detection times. <b>neighbor-negotiation</b> : Indicates neighbor negotiation.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Modify all RLDP parameters on all ports when necessary.

### ✚ Configuring A Time Interval for Recovering Failed Ports

<b>Command</b>	<code>rldp error-recover interval <i>interval</i></code>
<b>Parameter Description</b>	<b><i>interval</i></b> : Indicates a recovery interval. The unit is second. The range is from 30 to 86400. This function is disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to configure a time interval for recovering the state (Error state) of failed ports. If the loop is eliminated, the topology environment will be automatically recovered.

### ✚ Enabling RLDP Detection on Interface

<b>Command</b>	<code>rldp port { unidirection-detect   bidirection-detect   loop-detect } { warning   shutdown-svi   shutdown-port   block   monitor }</code>
<b>Parameter Description</b>	<b>unidirection-detect</b> : Indicates unidirectional link detection. <b>bidirection-detect</b> : Indicates bidirectional forwarding detection. <b>loop-detect</b> : Indicates downlink loop detection. <b>warning</b> : Indicate the failure treatment is warning. <b>shutdown-svi</b> : Indicate the failure treatment is closing the SVI that the interface is on. <b>shutdown-port</b> : Indicates the failure treatment is port violation. <b>block</b> : Indicates the failure treatment is disabling learning and forwarding of a port. <b>monitor</b> : Indicates the failure treatment is monitoring the port state.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The interfaces include layer-2 switch ports, layer-3 routed ports, layer-2 AP member ports, and layer-3 AP member ports. Ports on which RLDP is enabled to handle downlink loop failures are random. For example, RLDP downlink loop detection is configured on both downlink ports A and B, and the configured failure handling mode of port A is <b>warning</b> while that of port B is <b>shutdown-port</b> . When there is a downlink loop between port A and port B, port A may detect the downlink loop failure prior to port B. After port A completes failure handling according to the

	<p>configuration, it no longer sends packets to detect the downlink loop status. Port B fails to detect the downlink loop failure because it does not receive a loop detection packet from port A, but the downlink loop actually persists. If a detected downlink loop needs to be actually removed in application scenarios, downlink ports in the same loop must be restricted to use a consistent loop failure handling mode and the loop failure handling mode cannot be <b>warning</b>.</p> <p>The <b>monitor</b> policy can be configured for the unidirectional link detection in order to correlate with ERPS (Ethernet Ring Protection Switching).</p>
--	--

### ✎ Modifying Global RLDP Detection Parameters

<b>Command</b>	<b>rldp {detect-interval <i>interval</i>   detect-max <i>num</i>   neighbor-negotiation }</b>
<b>Parameter Description</b>	<p><b>detect-interval <i>interval</i></b>: Indicates a detection interval.</p> <p><b>detect-max <i>num</i></b>: Indicates detection times.</p> <p><b>neighbor-negotiation</b>: Indicates neighbor negotiation.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Modify all RLDP parameters on all ports when necessary.

### ✎ Recovering Failed Port

<b>Command</b>	<b>rldp reset</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Privileged mode
<b>Usage Guide</b>	Recover all failed ports to initialized state and resume detection.

### ✎ Displaying RLDP State Information

<b>Command</b>	<b>show rldp [ interface <i>interface-name</i> ]</b>
<b>Parameter Description</b>	<b><i>interface-name</i></b> : Indicates the interface to display information of.
<b>Command Mode</b>	Privileged mode, global configuration mode, or interface configuration mode
<b>Usage Guide</b>	Display RLDP state information.

## Configuration Example

### ✎ Enabling RLDP Detection in Ring Topology

	<p>As shown in the following figure, the aggregation and access sections are in a ring topology. The STP is enabled on all devices to prevent loop and provide redundancy protection. To avoid a unidirectional or bidirectional link failure resulting in STP failure, RLDP unidirectional and bidirectional link detection is enabled between aggregation devices as well as between an aggregation device and the access device. To avoid loop due to wrong downlink connection of the aggregation devices, enable RLDP downlink loop detection on the downlink ports of the aggregation devices and of the access device. To avoid loop due to wrong downlink connection of the access device, enable RLDP downlink loop detection on the downlink ports of the access device.</p>
--	--

<p><b>Figure 2-4</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● SW A and SW B are aggregation devices, and SW C is an access device. Users connected to SW C. SW A, SW B and SW C are structured in a ring topology, and the STP is enabled on each of them. For STP configuration, refer to relevant configuration guide.</li> <li>● Enable the RLDP on SW A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.</li> <li>● Enable the RLDP on SW B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.</li> <li>● Enable the RLDP on SW C, enable unidirectional and bidirectional link detection on the two uplink ports, and enable loop detection on the two downlink ports.</li> </ul>
<p><b>A</b></p>	<pre> A#configure terminal A(config)#rldp enable A(config)#interface GigabitEthernet 2/0/1 A(config-if-GigabitEthernet2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#exit A(config)#interface GigabitEthernet 2/0/9 A(config-if-GigabitEthernet2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port loop-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#exit </pre>
<p><b>B</b></p>	<p>Apply the configuration on SW A.</p>
<p><b>C</b></p>	<pre> C#configure terminal C(config)#rldp enable C(config)#interface GigabitEthernet 0/49 C(config-if-GigabitEthernet 0/49)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)# exit C(config)#interface GigabitEthernet 0/50 </pre>

	<pre> C(config-if-GigabitEthernet 0/50)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#exit C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)#rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/1)#exit C(config)#interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)#rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/2)#exit </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Check the RLDP information on SW A, SW B and SW C. Take SW A for example.</li> </ul>
<b>A</b>	<pre> A#show rldp  rldp state          : enable  rldp hello interval: 3  rldp max hello     2  rldp local bridge  : 00d0.f822.33aa  -----  Interface GigabitEthernet 2/0/1  port state         : normal  neighbor bridge   : 00d0.f800.51b1  neighbor port     : GigabitEthernet2/0/1  unidirection detect information:      action: shutdown-port      state : normal  bidirection detect information:      action: shutdown-port      state : normal  Interface GigabitEthernet 2/0/9  port state         : normal  neighbor bridge   : 00d0.f800.41b0  neighbor port     : GigabitEthernet 0/49  unidirection detect information:      action: shutdown-port      state : normal </pre>

	bidirection detect information: action: shutdown-port state : normal loop detect information: action: shutdown-port state : normal
--	---

### Common Errors

- RLDP functions and private multicast address authentication or TPP are enabled at the same time.
- Neighbor negotiation is not enabled when configuring unidirectional or bidirectional link detection. The RLDP should be enabled on a neighbor device, or otherwise a unidirectional or bidirectional failure will be detected.
- If RLDP detection is configured to be implemented after neighbor negotiation while configuring unidirectional or bidirectional link detection, detection cannot be implemented as no neighbor can be learned due to a link failure. In this situation, you are suggested to recover the link state first.
- You are suggested not to specify the failure treatment as Shutdown SVI under a routed port.
- You are suggested not to specify the failure treatment as Block for a port, on which a loop protection protocol is enabled, for example, the STP.

## 2.5 Monitoring

### Displaying

Description	Command
Displays RLDP state.	<b>show rldp [ interface <i>interface-name</i> ]</b>

## 3 Configuring DLDP

### 3.1 Overview

The Data Link Detection Protocol (DLDP) is a protocol used to quickly detect faulty Ethernet links.

A typical Ethernet link detection mechanism detects physical link connectivity through autonegotiation at the physical layer. Such a mechanism has limitations when detecting Layer-3 data communication exceptions despite normal physical connections.

DLDP provides reliable Layer-3 link detection information. After detecting a faulty link, DLDP shuts down the logical state of Layer-3 ports to realize fast Layer-3 protocol convergence.

### 3.2 Applications

Application	Description
Intra-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in the same

	network segment.
<u>Inter-Network Segment DLDP Detection</u>	The source IP address of the detected port and the detected IP address are in different network segments.

### 3.2.1 Intra-Network Segment DLDP Detection

#### Scenario

This section describes the basic DLDP application scenario where the source IP address of the detected port and the detected IP address are in the same network segment.

In Figure 3-1, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/2 Layer-3 port on Switch C are in the same network segment. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/2, enable DLDP on Gi 0/1 or Gi 0/2.

Figure 3-1

<b>Remarks</b>	Device A and Device C are switches. Gi 0/1 and Gi 0/2 are Layer-3 ports in the same network segment. B is a network in the same network segment as Gi 0/1 and Gi 0/2.
----------------	---

#### Deployment

- Enable DLDP on Gi 0/1 or Gi 0/2.

### 3.2.2 Inter-Network Segment DLDP Detection

#### Scenario

This section describes the DLDP application scenario where the source IP address of the detected port and the detected IP address are in different network segments.

In Figure 3-2 the Gi 0/1 Layer-3 port on Switch A and the Gi 0/4 Layer-3 port on Switch D are in different network segments. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/4, enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address (IP address of the Gi 0/2 port on Switch B).

Figure 3-2

<b>Remarks</b>	Device A, Device B, and Device D are switches. Gi 0/1 and Gi 0/4 are Layer-3 ports in different network segments.
----------------	--

## Deployment

- Enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address.

## 3.3 Features

### Basic Concepts

#### ↘ DLDP Detection Interval and Retransmission Times

Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.

Retransmission times: Indicate the maximum times DLDP detection packets can be retransmitted in the case of a DLDP detection failure.

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the retransmission times, the device determines that a Layer-3 link failure occurs and shuts down the logical state of its Layer-3 port (despite the normal physical link connection). When Layer-3 link connectivity is recovered, the device restores its Layer-3 port to Up logical state.

#### ↘ DLDP Detection Modes

Active mode and passive mode are two DLDP detection modes.

Active mode (default): ICMP detection packets are sent actively.

Passive mode: ICMP detection packets are received passively.

#### ↘ DLDP Next Hop

Next hop: Indicates the next node connected to the detected IP address in inter-network segment DLDP detection.

In some cases, DLDP needs to detect IP reachability in non-directly connected network segments. You need to configure the next-hop IP address for the detected port to allow DLDP to obtain the next-hop MAC address through an ARP packet before sending a correct ICMP packet.

In this situation, you need to avoid the return of the reply packet from another link; otherwise, DLDP will misjudge that the detected port does not receive an ICMP reply.

#### ↘ DLDP Recovery Times

Recovery times: Indicate the times DLDP needs to receive consecutive reply packets (ICMP reply) before it can determine link failure recovery.

In some cases, link detection may be unstable. For example, a link is only intermittently pingable. In this case, DLDP repeatedly changes the link status between Up and Down, which may further destabilize the ring network.

Recovery times indicate the times DLDP needs to receive consecutive reply packets before DLDP can set the link in Down state to Up. The default recovery times are three times, indicating that the link needs to be successfully pinged three times before it is set to Up. The recovery times setting reduces link

detection sensitivity but increases stability. Related parameters are adjustable according to the network condition.

## ↘ DLDP Bound MAC Address

Bound MAC address: Indicates the MAC address bound to the detected IP address.

In a complex network environment, DLDP may obtain an invalid MAC address if the detected link has abnormal ARP packets transmitted (causing ARP spoofing), which will make DLDP detection abnormal.

To address this problem, you can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

### Overview

Feature	Description
<a href="#">DLDP Detection</a>	Detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.
<a href="#">MAC Address Binding</a>	Binds the detected IP address to the MAC address of the detected device to avoid DLDP exceptions otherwise caused by ARP spoofing.
<a href="#">Passive DLDP Detection</a>	When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

### 3.3.1 DLDP Detection

DLDP detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the corresponding Layer-3 port.

#### Working Principle

After DLDP detection is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specific period, DLDP determines that the link is abnormal and sets the Layer-3 port to Down.

#### Related Configuration

##### ● Enabling DLDP Detection

By default, DLDP detection is disabled on ports.

Run the **dl dp** command with the detected IP address specified to enable DLDP detection.

You can configure the next-hop IP address, MAC address of the detected device, transmission interval, retransmission times, and recovery times based on the actual environment.

### 3.3.2 MAC Address Binding

The MAC address binding feature is used to bind the detected IP address (or next-hop IP address) to the MAC address of the detected device (or next-hop device) to avoid DLDP exceptions otherwise caused by ARP spoofing.

#### Working Principle

You can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

### Related Configuration

By default, no MAC address is bound in DLDP detection.

Bind the MAC address of the detected device when you run the **dldp** command to enable DLDP detection. If the next-hop IP address is specified, bind the MAC address of the next-hop device.

After DLDP detection is enabled, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address. If the source IP address and MAC address in the received packet do not match the bound IP address and MAC address, DLDP will not process the packet.

### 3.3.3 Passive DLDP Detection

When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

### Working Principle

After the device at the local end sends an ICMP echo packet, the peer device determines link connectivity according to the packet reception time by using specific detection parameters, which are the same as those at the local end, thus saving bandwidth and CPU resources.

### Related Configuration

By default, passive DLDP detection is disabled.

Run the **dldp passive** command to enable passive DLDP detection.

After passive DLDP detection is enabled, DLDP will return an ICMP reply packet upon receiving an ICMP echopacket, instead of actively sending ICMP echo packets to the peer end. If DLDP does not receive an ICMP echo packet within a specific period, it determines that the link to the peer port is abnormal.

## 3.4 Configuration

Configuration	Description and Command
<u>Enabling DLDP Detection</u>	 (Mandatory) It is used to enable DLDP detection in interface configuration mode.
	<b>dldp</b> Enables DLDP detection.
	 (Mandatory) It is used to enable passive DLDP detection in interface configuration mode.
	<b>dldp passive</b> Enables passive DLDP detection.
	 (Optional) It is used to configure the detection interval, retransmission times, and recovery times of DLDP detection in global configuration mode.
	<b>dldp interval</b> Modifies the DLDP parameters globally to apply
	<b>dldp retry</b> the modifications to DLDP detection on all
<b>dldp resume</b> ports.	

### 3.4.1 Enabling DLDP Detection

#### Configuration Effect

- Detect Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.

#### Notes

- DLDP supports the configuration of multiple IP addresses on a Layer-3 port. DLDP sets the port to Down when none of the IP addresses receives an ICMP reply. If one IP address resumes communication, DLDP sets the port to Up again.
- DLDP uses the first IP address of the Layer-3 port as the source IP address of detection packets.

#### Configuration Steps

##### ▾ Enabling DLDP Detection

- Mandatory.
- When you enable DLDP detection in interface configuration mode, you can configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment.

##### ▾ Configuring a DLDP Detection Mode

- Optional.
- You can configure active or passive DLDP detection in interface configuration mode based on the actual environment.
- If DLDP detection needs to be enabled at both ends of a Layer-3 link, you can configure passive DLDP detection at one end to save bandwidth and CPU resources.

##### ▾ Configuring DLDP Parameters Globally

- Optional.
- You can modify the parameters of DLDP detection on all ports in global configuration mode based on requirements. The parameters include the packet transmission interval, packet retransmission times, and recovery times.

#### Verification

- Display the device DLDP information, including the status and statistics of DLDP detection on all ports.

#### Related Commands

##### ▾ Enabling DLDP Detection

<b>Command</b>	<code>dldp ip-address [next-hop-ip] [mac-address mac-addr] [interval tick] [retry retry-num] [resume resume-num]</code>
<b>Parameter</b>	<i>ip-address</i> : Indicates the detected IP address.
<b>Description</b>	<p><i>next-hop-ip</i>: Indicates the next-hop IP address.</p> <p><i>mac-addr</i>: Indicates the MAC address of the detected device to be bound. If the next-hop IP address is specified, bind the MAC address of the next-hop device.</p> <p><i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s).</p> <p><i>retry-num</i>: The value ranges from 1 to 3,600. The default value is 4.</p>

	<i>resume-num</i> : Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The port to be enabled with DLDP detection must be a Layer-3 port, such as a router port, L3AP port, and SVI port.

### ▾ Configuring a DLDP Detection Mode

<b>Command</b>	<b>dldp passive</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	You need to enable DLDP detection before configuring a DLDP detection mode.

### ▾ Modifying DLDP Detection Parameters Globally

<b>Command</b>	<b>dldp { interval <i>tick</i>   retry <i>retry-num</i>   resume <i>resume-num</i> }</b>
<b>Parameter Description</b>	<i>tick</i> : Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s). <i>retry-num</i> : Indicates the interval at which detection packets are retransmitted. The value ranges from 1 to 3,600. The default value is 4. <i>resume-num</i> : Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Use this command to quickly modify the parameters of DLDP detection on all ports when the actual environment is changed.

### ▾ Displaying the DLDP Status

<b>Command</b>	<b>show dldp statistic [ interface <i>interface-name</i> ]</b>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the Layer-3 port on which the DLDP status will be displayed.
<b>Command Mode</b>	Privileged mode, global configuration mode, and interface configuration mode
<b>Usage Guide</b>	Use this command to display the DLDP status on a specific port. You can also use this command to display the DLDP status on all ports.

## Configuration Example

### ▾ Enabling DLDP Detection on Layer-3 Ports on Device A and Device B in a Layer-3 Network

<b>Scenario</b> Figure 3-3	
-------------------------------	--

<b>Verification</b>	<ul style="list-style-type: none"> <li>● Enable DLDP detection on the Gi 0/1 and Gi 0/2 router ports on Device A to detect the Layer-3 link connectivity between Device A and Device B and that between Device A and Device D.</li> <li>● To control the Gi 0/2 router port of Device B, enable passive DLDP detection on the port.</li> </ul>																								
<b>A</b>	<pre>A#configure terminal A(config)#interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#dldp 192.168.1.2 A(config-if-GigabitEthernet 0/1)# exit A(config)#interface GigabitEthernet0/2 A(config-if-GigabitEthernet 0/1)#dldp 192.168.3.4 192.168.2.3</pre>																								
<b>B</b>	<pre>B#configure terminal B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/1)#dldp 192.168.1.1 B(config-if-GigabitEthernet 0/1)#dldp passive</pre>																								
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Display the DLDP status on Device A and Device B to check whether DLDP detection is enabled and works normally.</li> </ul>																								
<b>A</b>	<pre>A# show dldp</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Type</th> <th>Ip</th> <th>Next-hop</th> <th>Interval</th> <th>Retry</th> <th>Resume</th> <th>State</th> </tr> </thead> <tbody> <tr> <td>Gi0/1</td> <td>Active</td> <td>192.168.1.2</td> <td></td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> <tr> <td>Gi0/1</td> <td>Active</td> <td>192.168.3.4</td> <td>192.168.2.3</td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> </tbody> </table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/1	Active	192.168.1.2		100	4	3	Up	Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/1	Active	192.168.1.2		100	4	3	Up																		
Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up																		
<b>B</b>	<pre>B# show dldp</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Type</th> <th>Ip</th> <th>Next-hop</th> <th>Interval</th> <th>Retry</th> <th>Resume</th> <th>State</th> </tr> </thead> <tbody> <tr> <td>Gi0/2</td> <td>Passive</td> <td>192.168.1.1</td> <td></td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> </tbody> </table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/2	Passive	192.168.1.1		100	4	3	Up								
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/2	Passive	192.168.1.1		100	4	3	Up																		

**Common Errors**

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured in inter-network segment DLDP detection.

### 3.5 Monitoring

#### Clearing

Description	Command
Clears DLDL statistics.	<b>clear dldp</b> [ <b>interface</b> <i>interface-name</i> [ <i>ip-address</i> ] ]

#### Displaying

Description	Command
Displays the DLDL status.	<b>show dldp</b> [ <b>interface</b> <i>interface-name</i> ]
Displays the DLDL statistics on the Up/Down port sates.	<b>show dldp statistic</b>

## 4 Configuring VRRP

### 4.1 Overview

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol.

VRRP adopts the master-backup design to ensure migration of functions from a Master router to a Backup one when the Master failed, without influencing internal and external data communication or modifying Local Area Network (LAN) configuration. A VRRP group maps multiple routers into a virtual router. VRRP ensures only one router at a moment on behalf of a virtual router transfers packets, which is the elected Master. If the Master fails, one of the Backup routers will replace it. Under VRRP, it seems that a host in a LAN uses only one router, and the routing remains functional even when the first-hop router fails.

- VRRP is applicable to LAN scenarios which require the redundancy of routing egresses.

#### Protocols and Standards

- RFC2338: Virtual Router Redundancy Protocol
- RFC3768: Virtual Router Redundancy Protocol (VRRP)
- RFC5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

### 4.2 Applications

Application	Description
<a href="#">Routing Redundancy</a>	Configure routers in a LAN as one VRRP group to achieve simple routing redundancy.
<a href="#">Load Balancing</a>	Configure routers in a LAN as multiple VRRP groups to achieve traffic load balancing.

#### 4.2.1 Routing Redundancy

##### Scenario

Configure routers in a LAN as one VRRP group, where hosts take the virtual IP address of this group as the default gateway address.

- Packets from Host 1, Host 2 and Host 3 to other networks are forwarded by the elected Master router (Router A in Figure 4-1).
- If Router A fails, the Master will be re-elected between Router B and Router C to forward packets, achieving simple routing redundancy.

Figure 4-1

### Deployment

- Router A, Router B and Router C are connected to the LAN via Ethernet interfaces.
- On Router A, Router B and Router C, VRRP is configured on the Ethernet interfaces connected to the LAN.
- These Ethernet interfaces are in the same VRRP group whose virtual IP address is 192.168.12.1.
- The gateway address for Host 1, Host 2 and Host 3 is the IP address of the VRRP group, namely 192.168.12.1.

### 4.2.2 Load Balancing

#### Scenario

Configure routers in a LAN as multiple VRRP groups. Hosts in the LAN take virtual IP addresses of the groups as their gateways, and each router backs up for other routers in different group.

- Packets from Host 1 and Host 2 to other networks with the default gateway address as the virtual IP address of virtual router 1 are forwarded by the Master of virtual router 1 (Router A in Figure 4-2).
- Packets from Host 3 and Host 4 to other networks with the default gateway address as the virtual IP address of virtual router 2 are forwarded by the Master of virtual router 2 (Router B in Figure 4-2).
- Routing redundancy is achieved on Router A and Router B, and the LAN traffic is shared to achieve load balancing.

Figure 4-2

## Deployment

- Router A and Router B are connected to the LAN via Ethernet interfaces.
- On Router A and Router B, two virtual routers are configured on the Ethernet interfaces connected to the LAN.  
Router A takes the IP address 192.168.12.1 of Ethernet interface Gi0/0 as the IP address of virtual router 1. Thus for virtual router 1, Router A becomes the Master and Router B becomes the Backup.
- Router B takes the IP address 192.168.12.2 of Ethernet interface Gi0/0 as the IP address of virtual router 2. Thus for virtual router 2, Router B becomes the Master and Router A becomes the Backup.
- In the LAN, Host 1 and Host 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while Host 3 and Host 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address.

## 4.3 Features

### Basic Concepts

#### Virtual Router

A virtual router, also called a VRRP group, is regarded as a default gateway for hosts in a LAN. A VRRP group contains a Virtual Router Identifier (VRID) and a set of virtual IP addresses.

#### Virtual IP Address

Indicates the IP address of a virtual router. A virtual router can be configured with one or multiple IP addresses.

#### IP Address Owner

If a VRRP group has the virtual IP address as that of an Ethernet interface on one real router, the router is regarded as the virtual IP address owner. In such case, the router priority is 255. If the owned Ethernet interface is available, the VRRP group will be in Master state automatically. The IP address owner receives and processes the packets with the destination IP address as that of the virtual router.

#### Virtual MAC Address

The virtual MAC address of a VRRP group is an IEEE 802 MAC address, formatted as **00-00-5E-00-01-{VRID}** with the first five octets assigned and the last two as a group VRID. A VRRP group responds to an Address Resolution Protocol (ARP) request with its virtual MAC address instead of a real MAC address.

#### ↘ Master Router

In a VRRP group, only the Master router answers ARP requests and forwards IP packets. If a real router is the IP Address Owner, it becomes the Master router.

#### ↘ Backup Router

In a VRRP group, Backup routers only monitor the state of the Master but do not respond to ARP requests or forward IP packets. When the Master fails, Backup routers will take the chance to compete for the position.

#### ↘ Preemption Mode

If a VRRP group runs in Preemption mode, a higher priority Backup router will replace the lower priority Master router.

#### Overview

Feature	Description
<u>VRRP</u>	VRRP achieves redundancy for the default gateways of terminals on a multi-access media (for example, Ethernet). It enables a Backup router to forward packets when the Master router is down, providing transparent routing switch and promoting network service quality.

### 4.3.1 VRRP

In case that the Master router is faulty, VRRP achieves migration of functions from the Master router to a Backup one without influencing internal and external data communication or modifying LAN configuration.

#### Working Principle

Figure 4-3 Working Principle of VRRP

#### ↘ Working Mode of VRRP

The RFC2338, RFC3768 and RFC5798 protocols define the format and operating mechanism of VRRP packets. Multicast VRRP packets are sent periodically with specified destination addresses by the Master router to advertise normal operation or for Master election. VRRP allows a router in a LAN to automatically replace the Master who forwards IP packets when the latter fails. This helps achieve hot

backup and fault tolerance of IP-based routing as well as ensure communication continuity and reliability for hosts in the LAN. A VRRP group achieves redundancy through multiple real routers. However, only one router acts as the Master to forward packets while the others are Backup routers. Router switching in a VRRP group is completely transparent to hosts in a LAN.

### ▼ Master Election Process

The RFC standards stipulate the master election process as follows:

- VRRP provides a simple mechanism for Master election. First, compare the VRRP priorities configured on the interfaces of the routers in a VRRP group. The router with the highest priority is elected as the Master. If these priorities are equal, compare the primary IP addresses of these routers. The router with the biggest IP address is elected as the Master.
- After the Master router is elected, the other routers become Backup routers (and enter the **Backup** state) and monitor the state of the master router through the VRRP packets the master router sends. If the master router is operational, it regularly sends VRRP multicast packets known as Advertisement packets to notify the Backup routers of its status. If the Backup routers do not receive such packets within a set period, all of them will enter the Master state. In such case, the previous step of Master election is repeated. In this way, a router with the highest priority will be elected as a new master, achieving VRRP backup.

Once the Master router of a VRRP group is elected, it is responsible to forward packets for hosts in a LAN.

### ▼ Communication Process

The VRRP communication process can be explained by Figure 4-3. The routers R1 and R2 are connected to the LAN segment 192.168.12.0/24 via the VRRP-enabled Ethernet interfaces Gi0/0. Hosts in the LAN take the virtual IP address of the VRRP group as the default gateway address. Only the virtual router is recognized by the hosts. The Master router in the group, however, is unknown. For example, when PC 1 plan to communicate with PC 2, PC 1 sends packets to the default gateway with the virtual IP address; The Master router in the group receives the packets and forwards them to PC 2. In this process, PC 1 only senses the virtual router instead of R1 or R2. The Master router in the group is elected between R1 and R2. When the Master fails, it will be replaced automatically by the other router.

## Related Configuration

### ▼ Enabling VRRP

By default, VRRP is disabled on an interface.

In the interface configuration mode, run the **vrrp group ip ipaddress [ secondary ]** or **vrrp group ipv6 ipv6-address** command to set the VRID and virtual IP address to enable VRRP.

VRRP must be enabled on an interface.

### ▼ Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode.

Run the **vrrp group authentication string** command to set an authentication string in MD5 authentication mode or a plain text password in plain text mode for an IPv4 VRRP group. In the plain text authentication mode, a password contains 8 bytes at most.

Members of a VRRP group can communicate with each other only when they are in the same authentication mode. In the plain text authentication mode, all routers in a VRRP group should have the

same authentication password. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations.

#### ↘ **Configuring the VRRP Advertisement Interval**

By default, the advertisement interval of the Master router is 1 second.

Run the `vrrp [ ipv6 ] group timers advertise { advertise-interval | csec centisecond-interval }` command to change the interval.

When VRRP learning timer is not configured, the same advertisement interval should be set for a VRRP group, otherwise routers in **Backup** state will discard received VRRP packets.

#### ↘ **Configuring the VRRP Preemption Mode**

By default, a VRRP group operates in the Preemption mode.

To enable the Preemption mode for a VRRP group, run the `vrrp [ ipv6 ] group preempt [ delay seconds ]` command. The optional parameter **delay seconds** is 0 by default.

If a VRRP group operates in the Preemption mode, a router will become the Master of the group when it finds that its priority is higher than that of the current Master. If a VRRP group operates in Non-preemption mode, a router will not become the Master even when it finds that its priority is higher than that of the current Master. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group. The optional parameter **Delay Seconds** defines the delay before a backup VRRP router declares its Master identity.

#### ↘ **Enabling the IPv6 VRRP Accept Mode**

By default, the Accept mode is disabled for an IPv6 VRRP group.

To enable the Accept mode, run the `vrrp ipv6 group accept_mode` command.

After the Accept mode is enabled, an IPv6 VRRP virtual router in **Master** state receives and processes packets with the virtual router IP address as the destination; when the Accept mode is disabled, the virtual router discards such packets except Neighbor Advertisement (NA) packets and Neighbor Solicitation (NS) packets. Besides, an IPv6 VRRP master virtual router in **Owner** state receives and processes packets with the virtual router IP address as the destination by default no matter whether the Accept mode is configured or not.

#### ↘ **Configuring the VRRP Router Priority**

By default, the router priorities in a VRRP group are all 100.

To adjust the priority, run the `vrrp [ ipv6 ] group priority level` command.

If a router in the Preemption mode owns the group's virtual IP address and the highest priority, it becomes the group Master, while the other routers with lower priorities in the group become Backup (or monitoring) routers.

#### ↘ **Configuring the VRRP Tracked Interface**

By default, no interface is tracked by a VRRP group.

To configure such an interface, run the **vrrp group track** { *interface-type interface-number* | **bfd interface-type interface-number ipv4-address** } [ *priority* ] or **vrrp ipv6 group track** *interface-type interface-number* [ *priority* ] command.

After an interface is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the interface state. Once the interface becomes unavailable, the priority of the router in the group will be reduced by a set value, and another functional and higher priority router in this group will become the Master.

#### ✚ Configuring the VRRP Tracked IP Address

By default, no IP address is tracked by a VRRP group.

To configure such an address, run the **vrrp group track** *ip-address* [ **interval** *interval-value* ] [ **timeout** *timeout-value* ] [ **retry** *retry-value* ] [ *priority* ] or **vrrp ipv6 group track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [ **interval** *interval-value* ] [ **timeout** *timeout-value* ] [ **retry** *retry-value* ] [ *priority* ] command.

After an IP address is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the address accessibility. Once the address is inaccessible (the **ping** command fails), the priority of the router in the group will be reduced by a set value, and another higher priority router in this group will become the Master.

#### ✚ Configuring the VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group.

To enable it, run the **vrrp [ ipv6 ] group timers learn** command.

After the learning timer is configured, a VRRP Backup router learns the advertisement interval of NA packets from the Master. Based on this instead of a locally set interval, the Backup router calculates the interval for determining a failure of the Master. This command achieves the synchronization of advertisement intervals between Backup routers and the Master.

#### ✚ Configuring the VRRP Group Description

By default, no description is configured for a VRRP group.

To configure such a string, run the **vrrp [ ipv6 ] group description** *text* command.

A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

#### ✚ Configuring the VRRP Delay

By default, no delay is configured for a VRRP group.

To enable it, run the **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* } command. The two types of delay range from 0 to 60 seconds.

The command configures the delay of starting a VRRP group on an interface. There are two types of VRRP delay: the delay after system startup and the delay after an interface resumes. You may configure them respectively or simultaneously. After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the

delay will be canceled and the VRRP will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

#### ✚ **Configuring the IPv4 VRRP Version**

By default, IPv4 adopts the VRRPv2 standard.

To specify the version for IPv4 VRRP, run the **vrrp group version { 2 | 3 }** command.

When the parameter value is set to 2, VRRPv2 is adopted; when the parameter value is set to 3, VRRPv3 is adopted.

#### ✚ **Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets**

By default, IPv4 VRRP packets are sent to the first **Up** Sub VLAN interface of a Super VLAN.

To specify the first Sub VLAN in Up state of a Super VLAN to receive IPv4 VRRP packets, run the **vrrp detection-vlan first-subvlan** command; to specify a Sub VLAN, run the **vrrp detection-vlan subvlan-id** command. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN.

Both the above configurations reduce VRRP packets and avoids influencing router performance and occupying network bandwidth. Yet the routers constituting an IPv4 VRRP group should be interconnected within the first UP Sub VLAN interface or a specified Sub VLAN of the Super VLAN.

#### ✚ **Configuring the BFD Support for IPv4 VRRP on an Interface**

By default, the Bidirectional Forwarding Detection (BFD) protocol support for VRRP is not enabled on an interface.

To enable it, run the **vrrp group bfd ip-address** command.

For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

After the BFD support is enabled for a specified IPv4 VRRP group, when the Master fails, a Backup router may detect it within one second.

#### ✚ **Configuring Global IPv4 VRRP BFD**

By default, the VRRP does not adopt the global IPv4 VRRP BFD mode in detecting the state of the Master.

To enable global IPv4 VRRP BFD, run the **vrrp bfd interface-type interface-number ip-address** command.

After global IPv4 VRRP BFD is enabled, multiple IPv4 VRRP groups may share BFD sessions, achieving fast detection and master-backup failover.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

## 4.4 Configuration

Configuration	Description and Command	
<u>Configuring IPv4 VRRP</u>	 (Mandatory) It is used to enable IPv4 VRRP.	
	<b>vrrp group ip</b> <i>ipaddress</i> [ <b>secondary</b> ]	Enables IPv4 VRRP.
	 (Optional) It is used to configure IPv4 VRRP parameters.	
	<b>vrrp group authentication</b> <i>string</i>	Configures the IPv4 VRRP authentication string.
	<b>vrrp group timers advertise</b> { <i>advertise-interval</i>   <b>csec</b> <i>centisecond-interval</i> }	Configures the IPv4 VRRP advertisement interval.
	<b>vrrp group preempt</b> [ <b>delay</b> <i>seconds</i> ]	Configures the IPv4 VRRP Preemption mode.
	<b>vrrp group priority</b> <i>level</i>	Configures the IPv4 VRRP router priority.
	<b>vrrp group track</b> { <i>interface-type interface-number</i>   <b>bfd</b> <i>interface-type interface-number ipv4-address</i> } [ <i>priority</i> ]	Configures the IPv4 VRRP tracked interface.
	<b>vrrp group track</b> <i>ip-address</i> [ <b>interval</b> <i>interval-value</i> ] [ <b>timeout</b> <i>timeout-value</i> ] [ <b>retry</b> <i>retry-value</i> ] [ <i>priority</i> ]	Configures the IPv4 VRRP tracked IP address.
	<b>vrrp group timers learn</b>	Configures the IPv4 VRRP learning timer.
	<b>vrrp group description</b> <i>text</i>	Configures the IPv4 VRRP group description.
	<b>vrrp delay</b> { <b>minimum</b> <i>min-seconds</i>   <b>reload</b> <i>reload-seconds</i> }	Configures the IPv4 VRRP delay.
	<b>vrrp group version</b> { <b>2</b>   <b>3</b> }	Configures the IPv4 VRRP version.
	<b>vrrp detection-vlan</b> { <b>first-subvlan</b>   <i>subvlan-id</i> }	Specifies a subVLAN of a superVLAN to receive the IPv4 VRRP packets.
	<b>vrrp group bfd</b> <i>ip-address</i>	Configures the BFD support for IPv4 VRRP on an interface.
<b>vrrp bfd</b> <i>interface-type interface-number ip-address</i>	Configures global IPv4 VRRP BFD.	
<u>Configuring IPv6 VRRP</u>	 (Mandatory) It is used to enable IPv6 VRRP.	
<b>vrrp group ipv6</b> <i>ipv6-address</i>	Enables IPv6 VRRP on the interface.	
 (Optional) It is used to configure IPv6 VRRP parameters.		
<b>vrrp ipv6 group timers advertise</b> { <i>advertise-interval</i>   <b>csec</b> <i>centisecond-interval</i> }	Configures the IPv6 advertisement interval.	
<b>vrrp ipv6 group preempt</b> [ <b>delay</b> <i>seconds</i> ]	Configures the IPv6 VRRP Preemption mode.	
<b>vrrp ipv6 group accept_mode</b>	Enables the Accept mode for an IPv6 VRRP group.	
<b>vrrp ipv6 group priority</b> <i>level</i>	Configures the IPv6 VRRP router priority.	
<b>vrrp ipv6 group track</b> <i>interface-type interface-number</i> [ <i>interface-priority</i> ]	Configures the IPv6 VRRP tracked interface.	
<b>vrrp ipv6 group track</b> { <i>ipv6-global-address</i>   { <i>ipv6-linklocal-address interface-type interface-number</i> } } [ <b>interval</b> <i>interval-value</i> ]	Configures the IPv6 VRRP tracked IP address.	

Configuration	Description and Command
	[ <i>timeout timeout-value</i> ] [ <i>retry retry-value</i> ] [ <i>priority</i> ]
	<b>vrrp ipv6 group timers learn</b> Configures the IPv6 VRRP learning timer.
	<b>vrrp ipv6 group description text</b> Configures the IPv6 VRRP group description.
	<b>vrrp delay { minimum <i>min-seconds</i>   reload <i>reload-seconds</i> }</b> Configures the IPv6 VRRP delay.
<a href="#">Configuring VRRP-MSTP</a>	 The configuration is the same as IPv4 VRRP configuration.

#### 4.4.1 Configuring IPv4 VRRP

##### Configuration Effect

- Configure a VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IP address.
- Configure multiple VRRP groups on an interface to achieve load balancing and offer more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

##### Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv4 address.
- To achieve mutual backup between multiple IPv4 VRRP groups, configure multiple IPv4 VRRP groups with identical VRRP configuration on different interface and configure different priorities for them so that they act as the master and backup groups mutually.
- Enable VRRP on Layer-3 interfaces.

##### Configuration Steps

###### ▾ Enabling IPv4 VRRP

- By default, IPv4 VRRP is disabled on an interface. You can enable it based on your demand.

###### ▾ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in non-authentication mode. You can enable plain text authentication mode based on your demand.

###### ▾ Configuring the IPv4 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

###### ▾ Configuring the IPv4 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

###### ▾ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

###### ▾ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface and the value of priority change is 10. To achieve fault monitoring through interface monitoring, please configure this item.

#### ✚ Configuring the IPv4 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

#### ✚ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

#### ✚ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

#### ✚ Configuring the IPv4 VRRP Version

- By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

#### ✚ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first UP Sub VLAN interface of a Super VLAN, but you may configure a specific Sub VLAN.

#### ✚ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the BFD support is not configured on an interface. To configure it, use the corresponding command.

#### ✚ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not enabled. To implement it, use the corresponding command.

#### Verification

- Run the **show vrrp** command to verify the configuration.

#### Related Commands

##### ✚ Enabling IPv4 VRRP

<b>Command</b>	<b>vrrp group ip <i>ipaddress</i> [ <b>secondary</b> ]</b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipaddress</i> : Indicates the IP address of a VRRP group. <b>secondary</b> : Indicates the secondary IP address of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

##### ✚ Configuring the IPv4 VRRP Authentication String

<b>Command</b>	<b>vrrp group authentication <i>string</i></b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group. <i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).

<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3.</p> <p>Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.</p>

#### ✚ Configuring the IPv4 VRRP Advertisement Interval

<b>Command</b>	<b>vrrp group timers advertise</b> { <i>advertise-interval</i>   <b>csec centisecond-interval</b> }
<b>Parameter Description</b>	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>advertise-interval</i>: Indicates the advertisement interval of a VRRP group (unit: second).</p> <p><b>csec centisecond-interval</b>: An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

#### ✚ Configuring the IPv4 VRRP Preemption Mode

<b>Command</b>	<b>vrrp group preempt</b> [ <i>delay seconds</i> ]
<b>Parameter Description</b>	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><b>delay seconds</b>: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

#### ✚ Configuring the IPv4 VRRP Router Priority

<b>Command</b>	<b>vrrp group priority</b> <i>level</i>
<b>Parameter Description</b>	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>level</i>: Indicates the priority of an interface in a VRRP group.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to manually configure the VRRP router priority.

#### ✚ Configuring the IPv4 VRRP Tracked Interface

<b>Command</b>	<b>vrrp group track</b> { <i>interface-type interface-number</i>   <b>bfd</b> <i>interface-type interface-number ipv4-address</i> } [ <i>priority</i> ]
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>interface-type interface-number</i> : Indicates the interface to be tracked. <b>bfd</b> <i>interface-type interface-number ipv4-address</i> : A specified adjacent IP address tracked through BFD. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

### ↘ Configuring the IPv4 VRRP Tracked IP Address

<b>Command</b>	<b>vrrp group track</b> <i>ipv4-address</i> [ <b>interval</b> <i>interval-value</i> ] [ <b>timeout</b> <i>timeout-value</i> ] [ <b>retry</b> <i>retry-value</i> ] [ <i>priority</i> ]
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>ipv4-address</i> : Indicates the IPv4 address to be tracked. <b>interval</b> <i>interval-value</i> : Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default. <b>timeout</b> <i>timeout-value</i> : Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. <b>retry</b> <i>retry-value</i> : Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

### ↘ Configuring the IPv4 VRRP Learning Timer

<b>Command</b>	<b>vrrp group timers learn</b>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

### ▾ Configuring the IPv4 VRRP Group Description

<b>Command</b>	<b>vrrp group description text</b>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>text</i> : Indicates the description of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

### ▾ Configuring the IPv4 VRRP Delay

<b>Command</b>	<b>vrrp delay { minimum <i>min-seconds</i>   reload <i>reload-seconds</i> }</b>
<b>Parameter</b>	<b>minimum <i>min-seconds</i></b> : Indicates the VRRP delay after an interface state changes.
<b>Description</b>	<b>reload <i>reload-seconds</i></b> : Indicates the VRRP delay after the system starts.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delays share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

### ▾ Configuring the IPv4 VRRP Version

<b>Command</b>	<b>vrrp group version { 2   3 }</b>
<b>Parameter</b>	<b>2</b> : Indicates VRRPv2.
<b>Description</b>	<b>3</b> : Indicates VRRPv3.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

### ▾ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

<b>Command</b>	<b>vrrp detection-vlan { first-subvlan   subvlan-id }</b>
<b>Parameter</b>	<b>first-subvlan</b> : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
<b>Description</b>	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

▾ **Configuring the BFD Support for IPv4 VRRP on an Interface**

<b>Command</b>	<code>vrrp group bfd ip-address</code>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>ip-address</i> : Indicates the interface IP address.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.  If global IPv4 VRRP BFD is configured, this configuration cannot be performed.  To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

▾ **Configuring Global IPv4 VRRP BFD**

<b>Command</b>	<code>vrrp bfd interface-type interface-number ip-address</code>
<b>Parameter</b>	<i>interface-type interface-number</i> : Indicates interface type and ID.
<b>Description</b>	<i>ip-address</i> : Indicates the interface IP address..
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted.  To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.  A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.

**Configuration Example**

▾ **Configuring an IPv4 VRRP Group and Tracked Interface**

<p><b>Scenario</b> Figure 4-4</p>	<p>The diagram illustrates a network topology with three routers (R1, R2, R3) and three workstations (A, B, C). R1 and R2 are connected to a common bus, which is connected to WorkStation A (192.168.201.221/24) and WorkStation C (192.168.201.227/24). R3 is connected to another common bus, which is connected to WorkStation B (192.168.12.216/24). The Internet cloud is connected to R1 (Gi 2/1), R2 (Gi 1/1), and R3 (Gi 0/0). IP addresses for the Internet connections are: R1 (202.101.90.63/24), R2 (60.154.101.3/24), and R3 (192.168.12.217/24). Other IP addresses shown include 192.168.201.217/24 for R1 Gi0/0, 192.168.201.213/24 for R2 Gi0/0, and 192.168.12.0/24 for R3 Gi0/0. A virtual IP address of 192.168.201.0/24 is associated with the R1/R2 bus.</p>
<b>Configuration</b>	<ul style="list-style-type: none"> <li>The cluster of Work Station A and Work Station B (192.168.201.0/24) uses the virtual IP address 192.168.201.1 of</li> </ul>

<b>Steps</b>	<p>the VRRP group constituted by the routers R1 and R2 as the gateway address to communicate with Work Station B (192.168.12.0 /24).</p> <ul style="list-style-type: none"> <li>● GigabitEthernet 2/1 on R1 is configured as the tracked interface.</li> <li>● No VRRP but an ordinary routing function is configured on R3.</li> </ul>
<b>R3</b>	<pre> R3#configure terminal R3(config)#interface GigabitEthernet 0/0 //The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 0/0)#no switchport R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0 R3(config-if-GigabitEthernet 0/0)#exit R3(config)#interface GigabitEthernet 1/1 //The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 1/1)#no switchport R3(config-if-GigabitEthernet 1/1)#ip address 60.154.101.5 255.255.255.0 R3(config-if-GigabitEthernet 1/1)#exit R3(config)#interface GigabitEthernet 2/1 //The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 2/1)#no switchport R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 2/1)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10 </pre>
<b>R1</b>	<pre> R1#configure terminal R1(config)#interface GigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120 R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/0)#vrrp 1 track GigabitEthernet 2/1 30 R1(config-if-GigabitEthernet 0/0)#exit R1(config)#interface GigabitEthernet 2/1 R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0 </pre>

	<pre>R1(config-if-GigabitEthernet 2/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10</pre>
<b>R2</b>	<pre>R2#configure terminal R2(config)#interface GigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#exit R2(config)#interface GigabitEthernet 1/1 // The command "no switchport" is only required for a switch. R2(config-if-GigabitEthernet 1/1)#no switchport R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 1/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10</pre>
<b>Verification</b>	<p>Run the <b>show vrrp</b> command to verify the configuration.</p> <ul style="list-style-type: none"> <li>● Check whether R1, which acts as the Master, reduces its VRRP priority from 120 to 90 when GigabitEthernet2/1 connected to the Wide Area Network (WAN) is unavailable. If yes, R2 becomes the Master.</li> <li>● Check whether R1 resumes its VRRP priority from 30 to 120 when GigabitEthernet2/1 connected to the WAN recovers. If yes, R1 is re-elected as the Master.</li> </ul>
<b>R1</b>	<pre>R1#show vrrp GigabitEthernet0/0-Group 1   State is Master   Virtual IP address is 192.168.201.1 configured   Virtual MAC address is 0000.5e00.0101   Advertisement interval is 3 sec   Preemption is enabled     min delay is 0 sec   Priority is 120   Master Router is 192.168.201.217 (local), priority is 120   Master Down interval is 10.59 sec</pre>

	Tracking state of 1 interface, 1 up: up GigabitEthernet 2/1 prioritydecrement=30
<b>R2</b>	<pre> R2#show vrrp GigabitEthernet0/0-Group 1   State is Backup   Virtual IP address is 192.168.201.1 configured   Virtual MAC address is 0000.5e00.0101   Advertisement interval is 3 sec   Preemption is enabled     min delay is 0 sec   Priority is 100   Master Router is 192.168.201.217 , priority is 120   Master Advertisement interval is 3 sec   Master Down interval is 10.82 sec </pre>

### Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

### Configuration Example

#### 📄 Configuring Multiple IPv4 VRRP Groups

**Scenario**  
**Figure 4-5**

**Configuration Steps**

- The user workstation cluster (192.168.201.0/24) uses the backup group constituted by the routers R1 and R2. The gateway for partial workstations (A for example) points to the virtual IP address 192.168.201.1 of the backup group 1, while that for other partial workstations (C for example) points to the virtual IP address 192.168.201.2 of the backup group 2. IPv4 multicast routing is enabled on all the routers.
- R1 acts as the master router in the group 2 and as a backup router in the group 1.
- R2 acts as a backup router in the group 2 and as a master router in the group 1.

**R3**

```

R3#configure terminal
R3(config)#interface GigabitEthernet 0/0
//The command "no switchport" is only required for a switch.
R3(config-if-GigabitEthernet 0/0)#no switchport
R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0
R3(config-if-GigabitEthernet 0/0)#exit
R3(config)#interface GigabitEthernet 1/1
//The command "no switchport" is only required for a switch.
R3(config-if-GigabitEthernet 1/1)#no switchport
R3(config-if-GigabitEthernet 1/1)#ip address 60.154.101.5 255.255.255.0
R3(config-if-GigabitEthernet 1/1)#exit
R3(config)#interface GigabitEthernet 2/1
// The command "no switchport" is only required for a switch.
    
```

	<pre> R3(config-if-GigabitEthernet 2/1)#no switchport  R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0  R3(config-if-GigabitEthernet 2/1)#exit  R3(config)#router ospf  R3(config-router)#network 202.101.90.0 0.0.0.255 area 10  R3(config-router)#network 192.168.12.0 0.0.0.255 area 10  R3(config-router)#network 60.154.101.0 0.0.0.255 area 10 </pre>
<b>R1</b>	<pre> R1#configure terminal  R1(config)#interface GigabitEthernet 0/0  R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0  R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3  R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1  R1(config-if-GigabitEthernet 0/0)#vrrp 2 priority 120  R1(config-if-GigabitEthernet 0/0)#vrrp 2 timers advertise 3  R1(config-if-GigabitEthernet 0/0)#vrrp 2 ip 192.168.201.2  R1(config-if-GigabitEthernet 0/0)#vrrp 2 track GigabitEthernet 2/1 30  R1(config-if-GigabitEthernet 0/0)#exit  R1(config)#interface GigabitEthernet 2/1  R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0  R1(config-if-GigabitEthernet 2/1)#exit  R1(config)#router ospf  R1(config-router)#network 202.101.90.0 0.0.0.255 area 10  R1(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
<b>R2</b>	<pre> R2#configure terminal  R2(config)#interface GigabitEthernet 0/0  R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0  R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1  R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3  R2(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120  R2(config-if-GigabitEthernet 0/0)#vrrp 2 ip 192.168.201.2  R2(config-if-GigabitEthernet 0/0)#vrrp 2 timers advertise 3  R2(config-if-GigabitEthernet 0/0)#exit  R2(config)#interface GigabitEthernet 1/1  R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 </pre>

#### 4.4.2 Configuring IPv6 VRRP

##### Configuration Effect

- Configure an IPv6 VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IPv6 address.
- Configure multiple IPv6 VRRP groups on an interface to achieve load balance and achieve more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

##### Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv6 address.

- To achieve mutual backup for multiple IPv6 VRRP backup groups, you need to configure multiple IPv6 VRRP groups with identical VRRP configuration on an interface and configure different priorities for them to make routers master and backup mutually.
- VRRP must be enabled on Layer-3 interfaces.

### Configuration Steps

#### ▾ Enabling IPv6 VRRP

- By default, IPv6 VRRP is not enabled on an interface. You can enable it based on your demand.

#### ▾ Configuring the IPv6 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

#### ▾ Configuring the IPv6 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

#### ▾ Enabling the Accept Mode for an IPv6 VRRP Group

- By default, the Accept mode is disabled for an IPv6 VRRP group. To require an IPv6 VRRP VRRP group in Master state to receive and process packets with the destination IP address as that of the virtual router, enable Accept mode.

#### ▾ Configuring the IPv6 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

#### ▾ Configuring the IPv6 VRRP Tracked Interface

- By default, no tracked interface is configured. You can modify the interval based on your demand.

#### ▾ Configuring the IPv6 VRRP Tracked IP Address

- By default, no tracked IPv6 address is configured and the value of priority change is 10. You can configure this function based on your demand.

#### ▾ Configures the IPv6 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

#### ▾ Configuring the IPv6 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

#### ▾ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

### Verification

- Run the **show vrrp** command to verify the configuration.

### Related Commands

### ✚ Enabling IPv6 VRRP

<b>Command</b>	<code>vrrp group ipv6 ipv6-address</code>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipv6-address</i> : Indicates the IPv6 address of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	IPv6 VRRP groups and IPv4 VRRP groups share a VRID range from 1 to 255. One VRID is applicable to an IPv4 VRRP group and an IPv6 VRRP group at the same time. The first configured address should be a link-local address, which can be deleted only after other virtual addresses.

### ✚ Configuring the IPv6 VRRP Advertisement Interval

<b>Command</b>	<code>vrrp ipv6 group timers advertise { advertise-interval   csec centisecond-interval }</code>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group. <i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). <i>csec centisecond-interval</i> : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information. According to the RFC standards, if an IPv6 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.

### ✚ Configuring the Preemption Mode

<b>Command</b>	<code>vrrp ipv6 group preempt [ delay seconds ]</code>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group. <i>delay seconds</i> : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.

### ✚ Enabling the Accept Mode for an IPv6 VRRP Group

<b>Command</b>	<code>vrrp ipv6 group accept_mode</code>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	By default, an IPv6 VRRP group in <b>Master</b> state is not permitted to receive packets with the destination IPv6 address

	as that of the VRRP group. However, it receives NA and NS packets no matter whether Accept mode is configured. Besides, the IP Address Owner in Master state receives and processes the packets with the destination IPv6 address as that of the VRRP group no matter whether Accept mode is configured or not.
--	---

### ✚ Configuring the IPv6 VRRP Router Priority

<b>Command</b>	<b>vrrp ipv6 group priority level</b>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>level</i> : Indicates the priority of a VRRP router.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to manually configure the VRRP router priority.

### ✚ Configuring the IPv6 VRRP Tracked Interface

<b>Command</b>	<b>vrrp ipv6 group track interface-type interface-number [ priority ]</b>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>interface-type interface-number</i> : Indicates the interface to be tracked. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

### ✚ Configuring the IPv6 VRRP Tracked IP Address

<b>Command</b>	<b>vrrp ipv6 group track { ipv6-global-address   ipv6-linklocal-address interface-type interface-number } [ interval interval-value ] [ timeout timeout-value ] [ retry retry-value ] [ priority ]</b>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>ipv6-global-address</i> : Indicates the IPv6 global unicast address. <i>ipv6-linklocal-address</i> : Indicates the IPv6 link-local address. <i>interface-type interface-number</i> : Indicates the interface to be tracked. <i>interval interval-value</i> : Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default. <i>timeout timeout-value</i> : Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. <i>retry retry-value</i> : Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode

<b>Usage Guide</b>	<p>To monitor a host, specify its IPv6 address for an IPv6 VRRP group.</p> <p>If the host IP address being tracked is a link-local address, specify a network interface.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>
--------------------	--

#### ↘ Configures the IPv6 VRRP Learning Timer

<b>Command</b>	<b>vrrp ipv6 group timers learn</b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

#### ↘ Configuring the IPv6 VRRP Group Description

<b>Command</b>	<b>vrrp ipv6 group description text</b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group. <i>text</i> : Indicates the description of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

#### ↘ Configuring the IPv4 VRRP Delay

<b>Command</b>	<b>vrrp delay { minimum <i>min-seconds</i>   reload <i>reload-seconds</i> }</b>
<b>Parameter Description</b>	<b>minimum <i>min-seconds</i></b> : Indicates the VRRP delay after an interface state changes. <b>reload <i>reload-seconds</i></b> : Indicates the VRRP delay after the system starts.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

### Configuration Example

#### ↘ Configuring an IPv6 VRRP Group and Tracked Interface

<p><b>Scenario</b></p> <p><b>Figure 4-6</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Host A and Host B access the Internet resources through the default gateway 2000::1/64.</li> <li>● FSA and FSB belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively.</li> <li>● FSA tracks the interface GigabitEthernet 0/2 connected to the Internet. When GigabitEthernet 0/2 is unavailable, FS A reduces its priority and FS B acts as a gateway.</li> </ul>
<p><b>FSA</b></p>	<pre> FSA#configure terminal FSA(config)#interface GigabitEthernet 0/1 FSA(config-if-GigabitEthernet 0/1)#no switchport FSA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 FSA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 FSA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 track GigabitEthernet 0/2 50 FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode </pre>
<p><b>FSB</b></p>	<pre> FSB#configure terminal FSB(config)#interface GigabitEthernet 0/1 FSB(config-if-GigabitEthernet 0/1)#no switchport FSB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 FSB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 FSB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode </pre>
<p><b>Verification</b></p>	<p>Run the <b>show vrrp</b> command to verify the configuration.</p> <ul style="list-style-type: none"> <li>● Check whether FSA, which acts as the Master router, reduces its VRRP group priority from 120 to 70 when it</li> </ul>

	<p>finds that the interface GigabitEthernet0/2 connected to WAN is unavailable. If yes, FSB becomes the Master.</p> <ul style="list-style-type: none"> <li>● Check whether FSA increases its VRRP group priority from 50 to 120 when it finds the interface GigabitEthernet 0/2 connected to WAN becomes available again. If yes, FSA becomes the Master again.</li> </ul>
<b>FSA</b>	<pre>FSA#show ipv6 vrrp 1 GigabitEthernet0/1-Group 1 State is Master Virtual IPv6 address is as follows:     FE80::1     2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled     min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up:     up GigabitEthernet 0/2 priority decrement=50</pre>
<b>FSB</b>	<pre>FSB#show ipv6 vrrp 1 GigabitEthernet0/1-Group 1 State is Backup Virtual IPv6 address is as follow:     FE80::1     2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled     min delay is 0 sec Priority is 100 Master Router is FE80::1234, priority is 120 Master Advertisement interval is 3 sec</pre>

Master Down interval is 10.82 sec

## Configuration Example

### Multiple VRRP Backup Groups (under IPv6)

Scenario  
Figure 4-7

Configuration  
Steps

- Host A and Host B access the Internet resources through the gateways 2000::1/64 and 2000::100/64 respectively.
- FSA and FS B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively.
- FSA and FS B belong to the backup group 2 of a virtual IPv6 router, and their virtual addresses are 2000::100/64 and FE80::100 respectively.
- FSA and FS B act as gateways and forward flows, being a backup router to each other.

FSA

```
FSA#configure terminal
FSA(config)#interface GigabitEthernet 0/1
FSA(config-if-GigabitEthernet 0/1)#no switchport
FSA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64
FSA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1
FSA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode
FSA(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100
FSA(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 100
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3
FSA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode
```

<b>FSB</b>	<pre> FSB#configure terminal  FSB(config)#interface GigabitEthernet 0/1  FSB(config-if-GigabitEthernet 0/1)#no switchport  FSB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64  FSB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1  FSB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode  FSB(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100  FSB(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 120  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3  FSB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>
<b>Verification</b>	Run the <b>show vrrp</b> command to verify the configuration.
<b>FSA</b>	<pre> FSA#show ipv6 vrrp  GigabitEthernet0/1-Group 1    State is Master    Virtual IPv6 address is as follows:      FE80::1      2000::1    Virtual MAC address is 0000.5e00.0201    Advertisement interval is 3 sec    Accept_Mode is enabled    Preemption is enabled      min delay is 0 sec    Priority is 120    Master Router is FE80::1234 (local), priority is 120    Master Advertisement interval is 3 sec    Master Down interval is 10.59 sec  GigabitEthernet 0/1 - Group 2    State is Backup    Virtual IPv6 address is as follows: </pre>

	Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::5678(local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec
--	--

#### 4.4.3 Configuring VRRP-MSTP

##### Configuration Effect

- Link-level and gateway-level backup are achieved and network robustness is improved greatly when MSTP and VRRP are applied simultaneously.

##### Notes

- configure the routers in a VRRP backup group with the same virtual IPv4 address.
- Enabled VRRP on a Layer 3 interface.

##### Configuration Steps

###### ▾ Enabling IPv4 VRRP

- By default, IPv4 VRRP is not enabled on an interface. To enable IPv4 VRRP, please configure this item.

###### ▾ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in a non-authentication mode. To enable plain text password authentication for VRRP, please configure this item.

###### ▾ Configuring the IPv4 VRRP Advertisement Interval

- By default, a master router sends VRRP GWADV packets at an interval of one second. To manually set a value, please configure this item.

###### ▾ Configuring the IPv4 VRRP Preemption Mode

- By default, VRRP groups work in the preemption mode with zero-second delay.

###### ▾ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

###### ▾ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface. To achieve fault monitoring through monitoring an interface, please configure this item.

###### ▾ Configuring the IPv4 VRRP Learning Timer

- By default, timed learning is not enabled for a VRRP backup group. To enable backup routers to learn the VRRP GWADV packets from a master router, please configure this item.

### ✚ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups conveniently, please configure this item.

### ✚ Configuring the IPv4 VRRP Delay

- By default, the VRRP delay for a VRRP group is not configured. Configure the delay to guarantee a stable transition from Non-preemption mode to Preemption mode.

### ✚ Configuring the IPv4 VRRP Version

- By default, the VRRPv2 standard is adopted for IPv4 VRRP packets. To modify it manually, please configure this item.

### ✚ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first UP Sub VLAN interface in a Super VLAN, but you may configure a specific Sub VLAN interface to send such packets.

### ✚ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the linkage between an IPv4 VRRP and BFD is not configured on an interface. To enable such linkage, please configure this item.

### ✚ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not used to detect whether a master router is active. To enable this, please configure this item.

### Verification

- Run the **show vrrp** command to verify the configuration.

### Related Commands

#### ✚ Enabling IPv4 VRRP

<b>Command</b>	<b>vrrp group ip ipaddress [ secondary ]</b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipaddress</i> : The IP address of a VRRP group. <b>secondary</b> : Indicates the secondary IP address of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

#### ✚ Configuring the IPv4 VRRP Authentication String

<b>Command</b>	<b>vrrp group authentication string</b>
<b>Parameter Description</b>	<i>group</i> : Indicates the VRID of a VRRP group. <i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication

	<p>password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3.</p> <p>Authentication is abolished for VRRPv3 packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.</p>
--	---

#### ↘ Configuring the IPv4 VRRP Advertisement Interval

<b>Command</b>	<b>vrrp group timers advertise</b> { <i>advertise-interval</i>   <b>csec</b> <i>centisecond-interval</i> }
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<p><i>advertise-interval</i>: Indicates the advertisement interval of a VRRP group (unit: second).</p> <p><b>csec</b> <i>centisecond-interval</i>: An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

#### ↘ Configuring the IPv4 VRRP Preemption Mode

<b>Command</b>	<b>vrrp group preempt</b> [ <i>delay seconds</i> ]
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<b>delay seconds</b> : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

#### ↘ Configuring the IPv4 VRRP Router Priority

<b>Command</b>	<b>vrrp group priority</b> <i>level</i>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>level</i> : Indicates the priority of an interface in a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to manually configure the priority of a VRRP group.

#### ↘ Configuring the IPv4 VRRP Tracked Interface

<b>Command</b>	<b>vrrp group track</b> { <i>interface-type interface-number</i>   <b>bfd</b> <i>interface-type interface-number ipv4-address</i> } [ <i>priority</i> ]
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.
<b>Description</b>	<i>interface-type interface-number</i> : Indicates the interface to be tracked.

	<b>bfd interface-type interface-number ipv4-address:</b> A specified adjacent IP address tracked through BFD. <b>priority:</b> Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

### ↘ Configuring the IPv4 VRRP Tracked IP Address

<b>Command</b>	<b>vrrp group track ipv4-address [ interval interval-value ] [ timeout timeout-value ] [ retry retry-value ] [ priority ]</b>
<b>Parameter Description</b>	<b>group:</b> Indicates the VRID of a VRRP group. <b>ipv4-address:</b> Indicates the IPv4 address to be tracked. <b>interval interval-value:</b> Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default. <b>timeout timeout-value:</b> Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. <b>retry retry-value:</b> Indicates the probe retries. If the probe packet is sent continually for retry-value times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. <b>priority:</b> Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

### ↘ Configuring the IPv4 VRRP Learning Timer

<b>Command</b>	<b>vrrp group timers learn</b>
<b>Parameter Description</b>	<b>group:</b> Indicates the VRID of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

### ↘ Configuring the IPv4 VRRP Group Description

<b>Command</b>	<b>vrrp group description text</b>
<b>Parameter</b>	<b>group:</b> Indicates the VRID of a VRRP group.

<b>Description</b>	<i>text</i> : Indicates the description of a VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

#### ↘ Configuring the IPv4 VRRP Delay

<b>Command</b>	<b>vrrp delay</b> { <b>minimum</b> <i>min-seconds</i>   <b>reload</b> <i>reload-seconds</i> }
<b>Parameter</b>	<b>minimum</b> <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
<b>Description</b>	<b>reload</b> <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delays share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

#### ↘ Configuring the IPv4 VRRP Version

<b>Command</b>	<b>vrrp group version</b> { <b>2</b>   <b>3</b> }
<b>Parameter</b>	<b>2</b> : Indicates VRRPv2.
<b>Description</b>	<b>3</b> : Indicates VRRPv3.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

#### ↘ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

<b>Command</b>	<b>vrrp detection-vlan</b> { <b>first-subvlan</b>   <i>subvlan-id</i> }
<b>Parameter</b>	<b>first-subvlan</b> : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
<b>Description</b>	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If both VRRP and VRRP PLUS are enabled on a Super VLAN interface, VRRP packets are sent to all the UP Sub VLAN interfaces of the Super VLAN interface. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

#### ↘ Configuring the BFD Support for IPv4 VRRP on an Interface

<b>Command</b>	<b>vrrp group bfd</b> <i>ip-address</i>
<b>Parameter</b>	<i>group</i> : Indicates the VRID of a VRRP group.

<b>Description</b>	<i>ip-address</i> : Indicates the interface IP address.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.  If global IPv4 VRRP BFD is configured, this configuration cannot be performed.  To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

📌 **Configuring Global IPv4 VRRP BFD**

<b>Command</b>	<code>vrrp bfd interface-type interface-number ip-address</code>
<b>Parameter</b>	<i>interface-type interface-number</i> : Indicates interface type and ID.
<b>Description</b>	<i>ip-address</i> : Indicates the interface IP address.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted.  To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.  A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.

**Configuration Example**

📌 **Configuring VRRP+MSTP**

<p><b>Scenario</b> Figure 4-8</p>						
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Enable MSTP on routers (switches A, B, C, D, E and F in this example). Configure VLAN-Instance mapping (mapping VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0), and configure gateways (Switch A and Switch B in this example) as the root bridges of corresponding instances.</li> <li>● Add the SVIs of all VLANs to corresponding VRRP backup groups, and configure gateways as the master and backup routers for corresponding backup groups. See configuration details in the following table.</li> </ul>					
	<b>Gateway</b>	<b>VLAN ID</b>	<b>SVI</b>	<b>Backup Group</b>	<b>Virtual IP Address</b>	<b>State</b>

Switch A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Configure the uplink port (port Gi 0/1 of Switch A and Switch B) of master routers as a monitored interface of master router.
- Step 1: Create VLAN. Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 respectively on Switch A and Switch B.
- Step 2: Configure MST regions. Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.
- Step 3: Configure Switch A as the root bridge for MST 0 and MST 1, and Switch B as the root bridge for MST 2.
- Step 4: Enable MSTP.
- Step 5: Configure SVIs of all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the groups. See configuration in the above table.
- Step 6: Configure master routers and backup routers for all the groups.
- Step 7: Configure the uplink ports of master routers as monitored ports of VRRP groups. Caution: Monitored ports should be Layer 3 ports.

Step 8: Configure the Internet interfaces of the core routers as AP interfaces.

**SwitchA**

```
//Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 on Switch A.
SwitchA#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchA(config)#vlan range 10,20,30,40
SwitchA(config-vlan-range)#exit

//Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.
SwitchA(config)#spanning-tree mst configuration
SwitchA(config-mst)#instance 1 vlan 10,20
%Warning:you must create vlans before configuring instance-vlan relationship
SwitchA(config-mst)#instance 2 vlan 30,40
%Warning:you must create vlans before configuring instance-vlan relationship
SwitchA(config-mst)#exit

//On Switch A, configure the priority of MST 0 and MST 1 as 4096, and that of MST 2 as 8192.
SwitchA(config)#spanning-tree mst 0 priority 4096
```

```
SwitchA(config)#spanning-tree mst 1 priority 4096
SwitchA(config)#spanning-tree mst 2 priority 8192
//Enabling MSTP
SwitchA(config)#spanning-tree
Enable spanning-tree.
//Configure SVIs of all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for
the groups.
SwitchA(config)#interface vlan 10

## 4.5 Monitoring

### Displaying

Description	Command
Displays the brief or detailed information of IPv4/IPv6 VRRP.	<b>show [ ipv6 ] vrrp [ brief   group ]</b>
Displays the information of an IPv4/IPv6 VRRP group on a specified interface.	<b>show [ ipv6 ] vrrp interface <i>type number</i> [ brief ]</b>
Displays the statistics of VRRP packets.	<b>show vrrp packet statistics [ interface-type interface-number ]</b>

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs VRRP errors, events, packets and status.	<b>debug [ ipv6 ] vrrp</b>
Debugs VRRP errors.	<b>debug [ ipv6 ] vrrp errors</b>
Debugs VRRP events.	<b>debug [ ipv6 ] vrrp events</b>
Debugs VRRP packets.	<b>debug vrrp packets [ acl <i>acl-id</i>   [ icmp   protocol ] interface <i>type number</i> [ group ] ]</b> <b>debug ipv6 vrrp packets [ acl <i>acl-name</i>   [ icmp   protocol ] interface <i>type number</i> [ group ] ]</b>
Debugs VRRP status.	<b>debug [ ipv6 ] vrrp state</b>

## 5 Configuring VRRP Plus

### 5.1 Overview

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway backup and load balancing in the IEEE 802.3 local area network (LAN).

A disadvantage of VRRP is that the router in backup state cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue.

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This greatly reduces the workload of the network administrator.

### 5.2 Applications

Application	Description
<a href="#">Enabling Load Balancing Within a VRRP Group</a>	Implement load balancing within a VRRP group without configuring multiple groups or configuring different default gateways for hosts.

#### 5.2.1 Enabling Load Balancing Within a VRRP Group

##### Scenario

Enable load balancing within a VRRP group without configuring without configuring multiple VRRP groups or configuring different default gateways for hosts.

As shown in Figure 5-1, configure data as follows:

- Configure a VRRP group that consists of Router A and Router B, and enable the VRRP Plus function.
- Configure the default gateway of each host as the master virtual IP address of the VRRP group.

Figure 5-1 Application topology of IPv4 VRRP Plus

- 58. Two layer-3 (L3) devices, Router A and Router B, form a VRRP Plus group, and the virtual IP address of the group is 192.168.12.1. Router A is the master device of VRRP and functions as a balancing virtual gateway (BVG). Router B is the backup device of VRRP and functions as a balancing virtual forwarder (BVF).
- 59. Host 1 to Host 4 are hosts in the LAN with the network segment 192.168.12.0/24. Their default gateway addresses are set to the virtual IP address 192.168.12.1 of the VRRP Plus group.
- 60. The load balancing policy is configured on the device to respond to the ARP requests sent from different hosts. For example, when Host 1 and Host 2 request the gateway ARP, the MAC address 0000.5e00.0101 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the gateway ARP, the MAC address 001A.A916.0201 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.

Figure 5-2 Application topology of IPv6 VRRP Plus

**Remarks**

61. Two L3 devices, Router A and Router B, form an IPv6 VRRP Plus group, and the virtual IPv6 addresses are fe80::8 and 2000::8. Router A is the master device of IPv6 VRRP and functions as a BVG. Router B is the backup device of IPv6 VRRP and functions as a BVF.
62. Host 1 to Host 4 are hosts in the LAN, and all their IPv6 gateway addresses are set to 2000::8.
63. When Host 1 and Host 2 request the neighbor discovery (ND) of the gateway, the MAC address 0000.5e00.0201 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the ND of the gateway, the MAC address 1414.4b72.7701 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.

**Deployment**

- Deploy VRRP Plus on Router A and Router B to implement load balancing on the local host.

**5.3 Features****Basic Concepts**

#### ▾ **BVG**

The BVG allocates virtual MAC addresses to members of the VRRP Plus group. It responds to the gateway ARP/ND requests in the LAN, and forwards packets of hosts in the LAN.

#### ▾ **BVF**

The BVF forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

**Overview**

Feature	Description
VRRP Plus	Extend VRRP and use VRRP to implement gateway backup and load balancing in the IEEE 802.3 LAN.

**5.3.1 VRRP Plus**

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to the virtual IP addresses of different VRRP groups.

**Basic Principles**

Hosts in a LAN use the unified gateway IP address (that is, virtual IP address of the VRRP group). When different hosts request the gateway ARP, the BVG responds with different virtual MAC addresses. In this way, traffic of different hosts are distributed to different members of the VRRP Plus group, thereby implementing load balancing.

#### ▾ **Relationship Between VRRP Plus and VRRP**

VRRP Plus relies on VRRP, and runs in the following way:

A master device in VRRP corresponds to a BVG in VRRP Plus, and a backup device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in the LAN are set to the virtual IP address of VRRP.

### ➤ **MAC Address Allocation Rules of the BVG and BVF**

The BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01-{VRID}, where VRID is the VRRP group number. The virtual MAC address used by a BVF is 00-1A-A9-16-{MemberID}-{VRID}, where MemberID is the member ID of the BVF in the VRRP Plus group. Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04. For an IPv6 VRRP Plus group, the BVG directly uses the virtual MAC address of IPv6 VRRP to ensure compatibility between IPv6 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-02-{VRID}, where VRID is the IPv6 VRRP group number. The virtual MAC address used by a BVF is 14-14-4B-72-{76 + MemberID}-{VRID}, where MemberID ranges from 01 to 03.

### ➤ **Load Balancing Policy of VRRP Plus**

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. Based on the specific load balancing policy, the BVG responds hosts with different virtual MAC addresses. There are three types of load balancing policies:

- **Host-dependent policy:** A specified virtual MAC address is used to respond to the requests sent by a specified host.
- **Round-robin policy:** Virtual MAC addresses in the backup group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- **Weighted policy:** The ARP/NA requests are responded based on the forwarding capability of each device.

If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the polling response mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode regardless of the earlier responses of the device. If the weighted policy is used, and the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded.

### ➤ **Proxy of the Virtual MAC Address**

When a device with a virtual MAC address becomes faulty in the backup group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted.

The BVG in the VRRP Plus backup group can quickly detect the fault, and automatically allocates the virtual MAC address of the faulty BVF to another device in the backup group. The new device acts as the proxy of the faulty device to forward packets of the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in the backup group can be called master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called proxy virtual MAC address.

### ➤ **Redirection Time and Timeout of the Proxy Virtual MAC Address**

VRRP Plus provides the proxy function for the virtual MAC address so that another device can take the place of a faulty device with a virtual MAC address to forward packets. If the BVF is recovered from the fault, its forwarding role is recovered and the BVF continues to forward packets of the virtual MAC

address allocated to this BVF. If the faulty BVF is not recovered, the backup group stops redirecting traffic to this virtual MAC address. That is, when ARP requests are received again, this virtual MAC address is no longer responded. After a sufficient long period of time, it is believed that hosts that use the MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. At this time, this virtual MAC address can be deleted, and packets sent to this virtual MAC address are dropped.

VRRP Plus supports configuration of the redirection time and timeout of the backup group. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address and stops using this virtual MAC address for proxy forwarding. Figure 1-3 shows the changes to the role of the virtual MAC address within the redirection time and timeout.

Figure 5-3 Changes to the Role of the Virtual MAC Address Within the Redirection Time and Timeout

### Weight-based Forwarding

VRRP Plus supports the weight configuration of the backup group. Different weights are configured for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices. When the weight of a BVF in the backup group is smaller than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies for the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.

### Association of VRRP Plus with BFD

VRRP Plus supports association with bidirectional forwarding detection (BFD) to adjust the weight based on the link status. Each device in a backup group can associate its weight with the link status. When a link is abnormal or interrupted, the device automatically decreases its weight. When the weight is too low, the device automatically exits from the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the

associated link recovers, the device can automatically restore its original weight and the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the recovered weight. IPv6 VRRP Plus currently does not support association with BFD.

### ↘ Weight-based Forwarding Seizure

VRRP Plus supports the function of seizing the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus backup group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the status of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding will take the place of the faulty device to forward packets. Assume that a VRRP Plus backup group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or the original forwarding role encounters a link failure and consequently degradation of forwarding performance. In this case, if the seizure mode is enabled, the fifth device can seize the forwarding role from a device with a smaller weight (that is, with lower forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This can minimize the waste of resources.

The BVG in a backup group is responsible for allocation of virtual MAC addresses. Therefore, the BVG role cannot be seized, and only the forwarding role of a BVF can be seized. If the BVG device is faulty, VRRP re-elects a new master device, which assumes the BVG role.

### ↘ Factors Affecting the Forwarding Policy

64. After VRRP Plus is configured, the ARP/NS requests are received from hosts can be responded based on different load balancing policies to implement load balancing among these hosts. However, load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before configuration of VRRP Plus. Therefore, if VRRP Plus is configured after the VRRP state is changed to Master, real load balancing cannot be implemented before aging of the ARP/NDs learned by hosts. Load balancing is implemented only after the gateway ARP/NDs recorded by the hosts age and the hosts request for new gateway addresses.
65. Periodical sending of gratuitous ARPs on an interface also affect the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARPs of VRRP virtual IP addresses will be disabled. When a virtual IP address overlaps with an actual IP address, gratuitous ARPs of this address are no longer sent.
66. When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict of the VRRP Plus virtual address occurs, sending gratuitous ARP/NA packet will result re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

## 5.4 Configuration

Configuration Item	Description and Command
--------------------	-------------------------

Configuration Item	Description and Command	
Configuring VRRP Plus	 (Mandatory) It is used to enable the VRRP Plus function.	
	<b>vrrp balance</b>	Enables the VRRP Plus function of a VRRP backup group with the specified group ID in interface configuration mode.
	 (Optional) It is used to configure parameters of a VRRP Plus backup group.	
	<b>vrrp load-balancing</b>	Configures the load balancing policy of VRRP Plus in interface configuration mode.
	<b>vrrp timers redirect</b>	Configures the redirection time and timeout of the proxy virtual MAC address in a VRRP Plus backup group in interface configuration mode.
	<b>vrrp weighting</b>	Configures the weight and upper and lower thresholds of a VRRP Plus backup group in interface configuration mode.
	<b>vrrp forwarder preempt</b>	Configures the forwarding seizure function of a VRRP Plus backup group in interface configuration mode.
	<b>vrrpweighting track</b>	Configures a weight tracking object of a VRRP Plus backup group in interface configuration mode.

#### 5.4.1 Configure VRRP Plus

##### Configuration Effect

- Enable the VRRP Plus function. (By default, this function is disabled.)
- Configure a weight tracking object of a VRRP Plus backup group.

##### Notes

- To enable the VRRP Plus function, you must configure the VRRP virtual IP address for the corresponding backup group.

##### Configuration Steps

###### ▾ Enabling VRRP Plus on an Interface

- By default, VRRP Plus is enabled. Perform this configuration if VRRP Plus is required.

###### ▾ Configuring the Load Balancing Policy of VRRP Plus

- After VRRP Plus is enabled, the host-dependent load balancing policy is used by default.

###### ▾ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

- After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default.

###### ▾ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the weight of the backup group is set to 100, the lower threshold to 1, and the upper threshold to 100 by default.

###### ▾ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the forwarding seizure function is enabled by default.

### ✚ Configuring the Weight Tracking Object of a VRRP Plus Backup Group

- The weight tracking object of a VRRP Plus backup group is disabled by default. Perform this configuration if the tracking function is required.

#### Verification

- Run the **show [ ipv6 ] group vrrp balance** command to display the VRRP backup group configuration. If the backup group has the packet forwarding tasks, "local" is displayed in the **forwarders** column, and the virtual MAC address allocated to this backup group is also displayed.

#### Related Commands

### ✚ Enabling VRRP Plus on an Interface

<b>Command</b>	<b>vrrp [ ipv6 ] group balance</b>
<b>Parameter</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4.
<b>Description</b>	<b>group:</b> Indicates the ID of the VRRP group. The value range of the group ID varies according to the product model.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	VRRP Plus can be enabled only after a VRRP group is configured.

### ✚ Configuring the Load Balancing Policy of a VRRP Plus Backup Group

<b>Command</b>	<b>vrrp [ ipv6 ] group load-balancing { host-dependent   round-robin   weighted }</b>
<b>Parameter</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4.
<b>Description</b>	<b>group:</b> Indicates the ID of the VRRP group. <b>host-dependent:</b> Indicates the host-dependent load balancing policy. <b>round-robin:</b> Indicates the round-robin load balancing policy. <b>weighted:</b> Indicates the weighted load balancing policy.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After VRRP Plus is enabled, the host-dependent load balancing policy is used by default. The load balancing policy of the entire backup group is determined by the policy configured on the BVG. If you wish to use the same load balancing policy after the role of the BVG device changes, configure the same policy on all devices in the backup group.

### ✚ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

<b>Command</b>	<b>vrrp [ ipv6 ] group timers redirect redirect-timeout</b>
<b>Parameter</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4.
<b>Description</b>	<b>group:</b> Indicates the ID of the VRRP group. <b>redirect:</b> Indicates the redirection time. The value ranges from 0 to 3,600s. The default value is 300s, that is, 5 minutes. <b>timeout:</b> Indicates the timeout time. The value ranges from (redirect+600) to 64,800s. The default value is 14400, that is, 4 hours.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the

	redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address.
--	--

### ↘ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

<b>Command</b>	<b>vrrp [ ipv6 ]group weightingmaximum [ lowerlower ] [ upperupper ]</b>
<b>Parameter Description</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. <b>maximum:</b> Indicates the weight of the backup group. The value ranges from 2 to 254. The default value is 100. <b>lower/lower:</b> Indicates the lower threshold of the backup group. The value ranges from 1 to (maximum - 1). The default value is 1. <b>upper/upper:</b> Indicates the upper threshold of the backup group. The value ranges from lower to maximum. The default value is 100.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After VRRP Plus is enabled, the weight and upper and lower thresholds of a VRRP Plus backup group are configured by default. You can use this command to configure different weights for different devices so that more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight. When the weight of a BVF in the backup group is lower than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is higher than the upper threshold, the forwarding role of the BVF is automatically restored.

### ↘ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

<b>Command</b>	<b>vrrp[ ipv6 ]group forwarder preempt</b>
<b>Parameter Description</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. <b>group:</b> Indicates the ID of the VRRP group.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After VRRP Plus is enabled, the forwarding seizure function is enabled by default. VRRP Plus supports configuration of the forwarding seizure function of a backup group. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state.

### ↘ Configuring the Weight Tracking Object of a VRRP Plus Backup Group

<b>Command</b>	<b>vrrp [ ipv6 ] group weighting track object-number [ decrement value ]</b>
<b>Parameter Description</b>	<b>ipv6:</b> Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. <b>group:</b> Indicates the ID of the VRRP group. <b>object-number:</b> Indicates the number of the tracking object. The value ranges from 1 to 700. <b>decrement value:</b> Indicates the decrement weight when the tracking object is down. The decrement value ranges from 1 to 255. The default value is 10.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After VRRP Plus is enabled, no tracking object is configured by default. After the tracking object is configured, the decrement value is 10 by default.

**Configuration Example**

**Enabling Load Balancing Within an IPv4 VRRP Group**

<p><b>Scenario</b></p>	<p>The diagram illustrates a network setup for load balancing. Two routers, Router A (BVG) and Router B (BVF), are connected to the Internet via their Gi 0/14 interfaces. They are also connected to a LAN via their Gi 0/0 interfaces. The LAN is a 192.168.12.0/24 network with a default gateway of 192.168.12.1. Four hosts (Host 1, Host 2, Host 3, Host 4) are connected to the LAN. Host 1 and Host 2 have a Gateway MAC of vmac1, while Host 3 and Host 4 have a Gateway MAC of vmac2.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure a tracking object respectively on Router A and Router B to track the status of the local GigabitEthernet 0/14 interface.</li> <li>● Configure a VRRP group and enable VRRP Plus respectively on Router A and Router B. Configure the local IP addresses so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device.</li> <li>● Configure the weighted load balancing policy. Configure the weight tracking object, and set the decrement value to 100.</li> <li>● Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding seizure of the backup group.</li> <li>● Set the default gateway addresses of Host 1 to Host 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.</li> </ul>
<p><b>Router A</b></p>	<pre> FSA#config FSA(config)#track 1 interface GigabitEthernet0/14 line-protocol FSA(config)#interface GigabitEthernet0/0 // 'no switchport' is used on the switch. FSA(config-if-GigabitEthernet 0/0)#no switchport FSA(config-if-GigabitEthernet 0/0)#ip address 192.168.12.3 255.255.255.0 FSA(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1 FSA(config-if-GigabitEthernet 0/0)#vrrp 1 balance FSA(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted FSA(config-if-GigabitEthernet 0/0)#vrrp 1 weighting track 1 decrement 100         </pre>
<p><b>Router B</b></p>	<pre> FSB#config FSB(config)#track 1 interface GigabitEthernet0/14 line-protocol FSB(config)#interface GigabitEthernet0/0         </pre>

	<pre>FSB(config-if-GigabitEthernet 0/0)#no switchport FSB(config-if-GigabitEthernet 0/0)#ip address 192.168.12.2 255.255.255.0 FSB(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1 FSB(config-if-GigabitEthernet 0/0)#vrrp 1 balance FSB(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted FSB(config-if-GigabitEthernet 0/0)#vrrp 1 weighting track 1 decrement 100</pre>
<b>Verification</b>	Run the <b>show vrrp balance</b> command to display the configuration of the VRRP Plus group. If the backup group has the packet forwarding tasks, "local" is displayed in the <b>forwarders</b> column, and the virtual MAC address allocated to this backup group is also displayed.
<b>Router A</b>	<pre>FSA# show vrrp balance interface GigabitEthernet0/0 State is BVG Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 Track object 1, state: up, decrement weight: 100 There are 2 forwarders Forwarder 1 (local) MAC address: 0000.5e00.0101 Owner ID is 0000.0001.0006 Preemption disabled (BVG cannot be preempted) Forwarder 2 MAC address: 001a.a916.0201 Owner ID is 00d0.f822.33a3 Preemption enabled</pre>
<b>Router B</b>	<pre>FSB# show vrrp balance interface GigabitEthernet0/0 State is BVF Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted</pre>

<p>Redirect time 300 sec, forwarder time-out 14400 sec</p> <p>Weighting 100 (configured 100), thresholds: lower 1, upper 100</p> <p>Track object 1, state: up, decrement weight: 100</p> <p>There are 2 forwarders</p> <p>Forwarder 1</p> <p>MAC address:</p> <p style="padding-left: 20px;">0000.5e00.0101</p> <p>Owner ID is 0000.0001.0006</p> <p>Preemption disabled (BVG cannot be preempted)</p> <p>Forwarder 2 (local)</p> <p>MAC address:</p> <p style="padding-left: 20px;">001a.a916.0201</p> <p>Owner ID is 00d0.f822.33a3</p> <p>Preemption enabled</p>
---

➤ **Enabling Load Balancing Within an IPv6 VRRP Group**

<p><b>Scenario</b> Figure 5-5</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an IPv6 VRRP group and enable IPv6 VRRP Plus respectively on Router A and Router B. Configure the priorities so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device.</li> <li>● Configure the weighted load balancing policy for the IPv6 VRRP Plus backup group.</li> <li>● Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding seizure of the backup group.</li> <li>● Set the default gateway addresses of Host 1 to Host 4 in the LAN to 2000::8.</li> </ul>
<p><b>Router A</b></p>	<pre>RouterA#config RouterA(config)#interface GigabitEthernet0/0 // 'no switchport' is used on the switch.</pre>

	<pre>RouterA(config-if-GigabitEthernet 0/0)#no switchport RouterA(config-if-GigabitEthernet 0/0)#ipv6 address 2000::6/64 RouterA(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 fe80::8 RouterA(config-if-GigabitEthernet 0/0)#vrrp 1 ipv62000::8 RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 priority 120 RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 load-balancing weighted RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 balance</pre>
<b>Router B</b>	<pre>RouterB#config RouterB(config)#interface GigabitEthernet0/0 RouterB(config-if-GigabitEthernet 0/0)#no switchport RouterB(config-if-GigabitEthernet 0/0)# ipv6 address 2000::7/64 RouterB(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6fe80::8 RouterB(config-if-GigabitEthernet 0/0)#vrrp 1 ipv62000::8 RouterB(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 load-balancing weighted RouterB(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 balance</pre>
<b>Verification</b>	<p>Run the <b>show ipv6 vrrp balance</b> command to display the configuration of the VRRP Plus group. **Common Errors**

- VRRP Plus does not take effect because the VRRP virtual IP address is not configured for the related group.

**5.5 Monitoring**

**Displaying**

Description	Command
-------------	---------

Displays the brief or detailed configuration of VRRP Plus.	<b>show [ ipv6 ] vrrp balance</b>
Displays the actions of the VRRP Plus group on a specified interface.	<b>show [ ipv6 ]vrrp balance interface</b>

## Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the VRRP Plus function.	<b>debug[ ipv6 ] vrrp balance</b>
Debugs errors.	<b>debug[ ipv6 ] vrrp balance error</b>
Debugs events of the VRRP Plus group.	<b>debug [ ipv6 ]vrrp balance event</b>
Debugs the messages between the VRRP module and the track module.	<b>debug[ ipv6 ] vrrp balance messages</b>
Debugs the VRRP Plus packets.	<b>debug[ ipv6 ]vrrp balance packets</b>
Debugs the VRRP Plus group status.	<b>debug [ ipv6 ] vrrp balance state</b>
Debugs the timers of the VRRP Plus group.	<b>debug vrrp balance timer</b>

## 6 Configuring BFD

### 6.1 Overview

Communication failures will interrupt networking and thus affect services. Therefore, it is essential to rapidly locate communication failures on links with adjacent devices to ensure a timely action and service availability. Bidirectional Forwarding Detection (BFD) provides a method of rapidly detecting connectivity of the forwarding path between two adjacent routers in an underloaded way. It can quickly spot faults on the bidirectional forwarding path between two routers for upper-layer protocols such as routing protocols and Multi-Protocol Label Switching (MPLS). As a result, a standby forwarding path is adopted to maintain the performance of the existing network.

#### Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multi-hop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

### 6.2 Applications

Application	Description
<u>BFD Support for OSPF</u>	OSPF utilizes BFD to rapidly detect the neighbor status.

BFD Support for Static Routing	Static routing utilizes BFD to rapidly detect the next-hop reachability of a route.
--------------------------------	---

## 6.2.1 BFD Support for OSPF

### Scenario

The Open Shortest Path First (OSPF) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, a BFD session is established with the neighbor in the full adjacency to detect the neighbor status. When the neighbor fails, OSPF immediately performs network convergence. The convergence time can be shortened from 120 seconds (by default, on a non-broadcast network, OSPF hello packets are transmitted at an interval of 30 seconds and the neighbor failure time is four times the interval, that is, 120 seconds) to 1 second.

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, OSPF is configured on the routers to establish routes, and BFD support for OSPF is enabled on the interfaces of Router A and Router B. When the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to OSPF, so as to trigger fast OSPF convergence.

Figure 6-1

<b>Remarks</b>	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.
----------------	--

### Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Run OSPF on Router A and Router B.
- Set BFD parameters on interconnected interfaces of Router A and Router B.
- Enable BFD support for OSPF on Router A and Router B.

## 6.2.2 BFD Support for Static Routing

### Scenario

BFD support for static routing prevents routers from selecting a faulty static route as the forwarding path and enables rapid routing failover by using an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the neighbor discovery (ND) mechanism. When BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session status. If a BFD session fails, the next hop of a static route is thought unreachable and will not be added to the routing information base (RIB).

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, static routing is configured on the routers to establish forwarding paths, and BFD support for static routing is enabled on the interfaces of Router A and Router B. When the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to static routing, so as to trigger the system to delete the static route from the RIB, thereby preventing routing errors.

Figure 6-2

<b>Remarks</b>	<p>A and B are routers.</p> <p>Switch is a Layer-2 switch.</p> <p>A and B are connected through the Layer-2 switch.</p>
----------------	---

### Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Configure static routing on Router A and Router B.
- Set BFD parameters for interconnected interfaces of Router A and Router B.
- Enable BFD support for static routing on Router A and Router B.

## 6.3 Features

### Basic Concepts

#### Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into control packets and echo packets. Echo packets concern only the local system of a BFD session. Therefore, their formats are not specified. BFD specifies the format of only control packets. Currently, there are two versions (version 0 and version 1) for the format of control packets. Version 1 is adopted by default for establishing a BFD session. If a device receives packets of version 0 from the peer system, the device automatically switches to version 0.

Figure 6-3

Field	Description
Vers	Indicates the BFD protocol version number, which is 1 currently.
Diag	Indicates the cause for the local system's last change in session state, including: 0 -- No Diagnostic. 1 -- Control Detection Time Expired 2 -- Echo Function Failed 3 -- Neighbor Signaled Session Down 4 -- Forwarding Plane Reset 5 -- Path Down 6 -- Concatenated Path Down 7 -- Administratively Down
Sta	Indicates the BFD local session state, including: 0 -- AdminDown. 1 -- Down. 2 -- Init. 3 -- Up.
P	Indicates that the transmitter in a BFD session adds this bit in a verification request upon parameter changes, waiting for the peer response.
F	Indicates the bit that must be set in the response packet for responding to the P bit.
C	Indicates the control plane independent. If set, changes of the control plane do not affect BFD detection. For example, if the control plane is OSPF, when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link status.
A	Indicates the authentication present. If set, a session is to be authenticated.
D	Indicates the demand request. If set, the transmitter desires to detect links in Demand mode.
M	Indicates the multipoint bit to be used in point-to-multipoint extensions. It must be set to 0 currently.
Detect Mult	Indicates the detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Indicates the packet length.
My Discriminator	Indicates the discriminator of the local end connected by a BFD session.
Your Discriminator	Indicates the discriminator of the remote end connected by a BFD session.
Desired Min Tx Interval	Indicates the minimum interval of transmitting BFD packets supported by the local end.
Required Min RX Interval	Indicates the minimum interval of receiving BFD packets supported by the local end.
Required Min Echo RX	Indicates the minimum interval of receiving echo packets supported by the local end. It is set to 0 if the

Field	Description
Interval	local end does not support the echo function.
Auth Type	(Optional) Indicates the authentication type, including: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Indicates the authentication data length.
Authentication Data	Indicates the authentication data area.

### ▾ Session Status

A BFD session can be in any of the four basic states: Down, Init, Up, and AdminDown.

- 67. Down: Indicates that a session is in the Down state or is established just now.
- 68. Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the Up state.
- 69. Up: Indicates that a session has been negotiated successfully.
- 70. AdminDown: Indicates that a session is in the AdminDown state.

BFD migrates the state machine based on the local session state and received BFD packets from the peer end.

A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the status change.

### ▾ Transmission Interval and Detection Time

Both ends negotiate BFD parameters during the establishment of a BFD session, to determine the transmission interval and detection time.

After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

### Overview

Feature	Description
<a href="#">BFD Session Establishment</a>	Establishes a BFD session.
<a href="#">BFD Session Detection</a>	Rapidly detects a bidirectional forwarding path.
<a href="#">BFD Support for Applications</a>	Rapidly advertises the BFD detection result.
<a href="#">BFD Protection</a>	Protects BFD from attacks for stability.
<a href="#">BFD Flapping Dampening</a>	Protects stability of associated applications in the case of line instability.

#### 6.3.1 BFD Session Establishment

BFD detection starts from the establishment of a BFD session.

#### Working Principle

## Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify a neighbor to establish a session.

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-4

BFD session establishment process:

71. OSPF discovers a neighbor and establishes a connection with the neighbor.
72. OSPF instructs BFD to establish a session with the neighbor.
73. BFD establishes a session with the neighbor.

## BFD Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- **Active mode**  
Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.
  - **Passive mode**  
BFD does not actively transmit a control packet for establishing a BFD session before a session is established but wait till it receives a control packet for establishing a BFD session from the peer end.
- i** The passive mode is not supported currently.

## Negotiation of BFD Session Parameters

Both ends negotiate BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

74. BFD session parameters (including **Desired Min Tx Interval**, **Required Min RX Interval**, and **Detect Mult**) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established.
75. Interfaces at both ends negotiate BFD session parameters and detect the session based on the parameters during the establishment of a BFD session.
76. After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

### 6.3.2 BFD Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is Down and notifies the associated application to accelerate the convergence.

#### Working Principle

##### ↘ Detection Process

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-5

Handling procedure after a BFD session is Down:

77. The link between Router A and Switch fails.
78. The BFD session between Router A and Router B is Down.
79. BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
80. OSPF processes the neighbor Down situation. If a backup forwarding path is available, it starts protocol convergence to enable the alternative forwarding path.

##### ↘ Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is Down.

- Query mode

In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If a system fails to receive a returned packet within the detection time, it advertises that the session is Down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several

consecutive echo packets within the detection time, it advertises that the session is Down. The echo function can be used together the preceding two detection modes. The echo packet detection function does not require the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. The enabling of the echo function in asynchronous mode can greatly reduce transmission of control packets because the detection is accomplished by the echo function. The enabling of the echo function in query mode can thoroughly cancel transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

-  The query mode is not supported and cannot be configured at present.
-  Only BFD session version 1 supports the BFD echo mode.
-  The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.

### 6.3.3 BFD Support for Applications

By BFD support, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened within 1 second.

#### Working Principle

After BFD support for a certain application is enabled, a BFD session is established based on the BFD configuration. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process, thereby improving its convergence. Currently, BFD supports the following applications:

- BFD support for RIP

After BFD support for the Routing Information Protocol (RIP) is enabled, RIP can utilize the BFD fault detection, which is faster than the ND mechanism of RIP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

  -  For more details about BFD support for RIP, see *Configuring RIP*.
- BFD support for OSPF

After BFD support for OSPF is enabled, OSPF can utilize the BFD fault detection, which is faster than the ND mechanism of OSPF, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

  -  For more details about BFD support for OSPF, see *Configuring OSPF*.
- BFD support for OSPFv3

After BFD support for OSPFv3 is enabled, OSPFv3 can utilize the BFD fault detection, which is faster than the ND mechanism of OSPFv3, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

  -  For more details about BFD support for OSPFv3, see *Configuring OSPFv3*.
- BFD support for BGP

After BFD support for the Border Gateway Protocol (BGP) is enabled, BGP can utilize the BFD fault detection, which is faster than the ND mechanism of BGP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

**i** For more details about BFD support for BGP, see *Configuring BGP*.

- BFD support for IS-IS

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, IS-IS uses BFD to establish a BFD session with a neighbor that is in the Up state and detect the neighbor status. When a BFD neighbor fails, IS-IS immediately performs network convergence. The convergence time can be shortened from 30 seconds (by default, on a point-to-point network, IS-IS hello packets are transmitted at an interval of 10 seconds and the neighbor failure time is triple the interval, that is, 30 seconds) to 1 second.

**i** For more details about BFD support for IS-IS, see *Configuring IS-IS*.

- BFD support for static routing

After BFD support for static routing is enabled, BFD prevents routers from selecting an unavailable static route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the ND mechanism. Therefore, after BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session state. If a BFD session detects a fault, the next hop of a static route is unreachable and the static route is not added to the RIB.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the forwarding behavior of static routing is not affected.

**i** For more details about BFD support for static routing, see *Configuring NSM*.

- BFD support for PBR

After BFD support for PBR is configured, BFD prevents routers from selecting an unavailable policy route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

BFD support for PBR is equivalent to that for static routing. BFD tracks and detects the forwarding path to a specified neighbor. When a BFD session fails, BFD notifies the PBR that the next hop is unreachable. Then, the policy route to the next hop does not take effect.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the PBR forwarding behavior is not affected.

**i** For more details about BFD support for PBR, see *Configuring PBR*.

- BFD support for VRRP

The BFD support for the Virtual Router Redundancy Protocol (VRRP) can replace the ND mechanism of VRRP to rapidly detect the running status of the active and standby routers. When a fault occurs, it accelerates the active/standby router switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP can also utilize BFD to track a specified neighbor. If the forwarding path to the neighbor fails during a BFD session, it automatically lowers the VRRP priority to a certain extent to trigger active/standby router switching. This configuration takes effect only when the dynamic routing protocol or other applications notify BFD to establish a session with a neighbor.

**i** For more details about BFD support for VRRP, see *Configuring VRRP*.

- BFD support for VRRP Plus

The BFD support for VRRP Plus can replace the BVF detection conducted by the balancing virtual gateway (BVG) of VRRP Plus to rapidly detect the running status of balancing virtual functions (BVs). When a fault occurs, it accelerates the forwarding entity switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

**i** For more details about BFD support for VRRP Plus, see *Configuring VRRP Plus*.

- BFD support for MPLS

The BFD support for Multiple protocol Label Switching (MPLS) refers that label switched paths (LSPs) use BFD to rapidly detect the neighbor status. The following detection modes are supported:

1. BFD detects static LSPs.
2. BFD detects LSPs generated by the Label Distribution Protocol (LDP).
3. BFD can detect reverse links of LSPs by using the IP protocols.

**i** For more details about BFD support for MPLS, see *Configuring MPLS*.

- BFD support for Layer-3 interfaces

BFD supports changing status of Layer-3 interfaces. In interface configuration mode, use the **bfd bind peer-ip** command to detect the direct address of a specified Layer-3 interface. After this CLI command is executed, a BFD session is created and the status of a Layer-3 interface can be changed based on the detection result of the BFD session, for example, BFD Down or BFD Up. This function is often used in various types of fast reroute (FRR), which uses BFD to detect the interface status to implement fast FRR switching.

**i** Only LDP FRR switching is supported in BFD support for Layer-3 interfaces.

- BFD support for L3AP member ports

After BFD support for Layer-3 access point (L3AP) member ports is enabled, BFD can rapidly detect a fault occurring on a member port link so that traffic on this link is rapidly distributed to other effective member links. In general, the fault detection time can be shortened within 1 second.

**i** For more details about BFD support for L3AP member ports, see *Configuring AP*.

### 6.3.4 BFD Protection

The BFD protection is used to protect BFD against session flapping caused by attacks (for example, a large number of ping packets attack devices).

#### Working Principle

The BFD protocol is very sensitive. If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD sessions flap, the BFD protection can be configured to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.

### 6.3.5 BFD Flapping Dampening

A BFD session may frequently switch over between Down and Up due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths and the running services are affected. The BFD flapping dampening can solve this problem.

#### Working Principle

A BFD session may frequently switch over between Down and Up. This function allows users to set the delay for status change advertisement. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies an associated application of BFD Down.

## 6.4 Configuration

Configuration	Description and Command	
<a href="#">Configuring BFD Basic Functions</a>	 (Mandatory) It is used to establish a BFD session.	
	<b>bfd interval</b>	Sets BFD parameters.
	N/A	Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides.
	 (Optional) It is used to configure the BFD detection mode, slow timer, and BFD support for Layer-3 interfaces.	
	<b>bfd echo</b>	Configures the BFD echo mode.
	<b>bfd slow-timer</b>	Configures the BFD slow timer.
	<b>bfd bind peer-ip</b>	Configures the BFD support for Layer-3 interfaces.
<a href="#">Configuring BFD Protection</a>	 (Optional) It is used to protect BFD against attacks.	
	<b>bfd cpp</b>	Enables BFD protection.
<a href="#">Configuring BFD Flapping Dampening</a>	 (Optional) It is used to protect associated protocols against BFD flapping.	
	<b>bfd up-dampening</b>	Configures BFD flapping dampening.

### 6.4.1 Configuring BFD Basic Functions

#### Configuration Effect

- Configure BFD support for applications.
- Establish a BFD session.
- A BFD session detects link faults.

#### Notes

- Pay attention to the following points when setting BFD session parameters:
  1. It is recommended that parameter settings be consistent at both ends of a BFD session, to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding due to different dampening time at both ends.
  2. Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.
- Pay attention to the following points when configuring BFD support for applications:

1. Ensure that it is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application requires BFD to establish a session with a neighbor, the BFD session can also be established.
  2. If the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established.
- Pay attention to the following points when configuring the BFD detection mode:
    1. In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, configure Quality of Service (QoS) policies to ensure that echo packets are processed preferentially or disable the echo function.
    2. The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hops.
    3. The echo mode takes effect only after this mode is enabled at both ends of a BFD session.
    4. Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the **no ip deny land** command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

## Configuration Steps

### ▾ Setting BFD Parameters

- Mandatory.
- BFD parameters need to be set at BFD session egresses of routers at both ends detected by BFD if no special requirements are raised.
- Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.

<b>Command</b>	<b>bfd interval</b> <i>milliseconds</i> <b>min_rx</b> <i>milliseconds</i> <b>multiplier</b> <i>interval-multiplier</i>
<b>Parameter Description</b>	<b>interval</b> <i>milliseconds</i> : Indicates the minimum TX interval, with the unit of milliseconds. <b>min_rx</b> <i>milliseconds</i> : Indicates the minimum RX interval, with the unit of milliseconds. <b>multiplier</b> <i>interval-multiplier</i> : Indicates the detection timeout multiplier.
<b>Defaults</b>	No BFD session parameter is configured.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The fast forwarding function must be enabled before the BFD function is enabled on routers.

### ▾ Enabling the BFD Echo Mode

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured.
- Complete the configuration on ports of switches or routers.
- A session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode.

<b>Command</b>	<b>bfd echo</b>
----------------	-----------------

<b>Parameter Description</b>	N/A
<b>Defaults</b>	The BFD echo mode is disabled.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<p>This command cannot be configured on AP interfaces.</p> <p>By default, when BFD session parameters are set, the system automatically enables the echo mode.</p> <p>The minimum TX interval and minimum RX interval of echo packets adopt the <b>Interval milliseconds</b> and <b>min_rx milliseconds</b> parameters of a session.</p> <p>Before enabling the echo mode of BFD, run the <b>no ip redirects</b> command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the <b>no ip deny land</b> command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).</p>

### ↘ Configuring the BFD Slow Timer

- (Optional) The default slow timer is 3,000 milliseconds. The value can be changed as required.
- Configure this function in global configuration mode of switches or routers.
- In BFD echo mode or session building, the slow timer is used to control packets. If the value increases, the required time for negotiating and establishing a BFD session becomes longer, and the time required for transmitting slow BFD packets in echo mode is longer.

<b>Command</b>	<b>bfd slow-timer [ milliseconds ]</b>
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the BFD slow timer, with the unit of milliseconds. The value ranges from 1,000 to 30,000 and the default value 3,000 is adopted if it is not set.
<b>Defaults</b>	The transmission interval of slow control packets is 3,000 milliseconds.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to specify the slow timer in echo mode.

### ↘ Configuring the BFD Support for Layer-3 Interfaces

- (Optional) Currently, this function is used only when MPLS LDP is used for FRR.
- Configure this function on interfaces of switches or routers.

<b>Command</b>	<b>bfd bind peer-ip src-address [source-ip dst-address] process-pst</b>
<b>Parameter Description</b>	<i>src-address</i> : Indicates the peer IP address of an interface. <i>dst-address</i> : Indicates the local IP address of an interface.
<b>Defaults</b>	BFD support for Layer-3 interfaces is not configured by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to enable BFD support for Layer-3 interfaces so as to rapidly detect connectivity of Layer-3 interfaces.

### ↘ Configuring the BFD Support for Applications

- Mandatory.

- This function is disabled by default.
- The configuration command varies with the associated applications. For details, see their configuration guides.
- This function must be configured at both ends so that a BFD session can be established.
- In RIP routing configuration mode, run the **bfd all interfaces** command to enable BFD support for RIP on all interfaces. For details, see *Configuring RIP*.
- In OSPF routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPF on all interfaces. For details, see *Configuring OSPF*.
- In OSPFv3 routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPFv3 on all interfaces. For details, see *Configuring OSPFv3*.
- In BGP routing configuration mode, run the **neighbor address fall-over bfd** command to enable BFD support for BGP. For details, see *Configuring BGP*.
- In IS-IS routing configuration mode, run the **bfd all interfaces** command to enable BFD support for IS-IS on all interfaces. For details, see *Configuring IS-IS*.
- In global configuration mode, run the **ip route static bfd [ vrf vrf-name ] interface-type interface-number gateway [ source ip-address ]** command to enable BFD support for static routing. For details, see *Configuring NSM*.
- In global configuration mode, run the **ipv6 route static bfd [ vrf vrf-name ] interface-type interface-number gateway [ source ip-address ]** command to enable BFD support for IPv6 static routing. For details, see *Configuring NSM*.
- Run the **set ip next-hop verify-availability next-hop-address bfd [ vrf vrf-name ] interface-type interface-number gateway** command to enable BFD support for PBR. For details, see *Configuring PBR*.
- Run the **set ipv6 next-hop verify-availability next-hop-address bfd [ vrf vrf-name ] interface-type interface-number gateway** command to enable BFD support for IPv6 PBR. For details, see *Configuring PBR*.
- Run the **vrrp bfd interface-type interface-number ip-address** command to enable BFD support for VRRP. For details, see *Configuring VRRP*.
- VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus. Only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

**Verification**

- The verification command varies with the associated applications. For details, see their configuration guides.

**Configuration Example**

▾ **Configuring BFD support for OSPF**

<p><b>Scenario</b> Figure 6-6</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure IP addresses for interconnected interfaces of Router A and Router B.</li> <li>● Run OSPF on Router A and Router B.</li> <li>● Set BFD parameters for interconnected interfaces of Router A and Router B.</li> </ul>

	<ul style="list-style-type: none"> <li>● Enable BFD support for OSPF on Router A and Router B.</li> </ul>
<b>A</b>	<pre> A#configure terminal A(config)#interface GigabitEthernet2/1 A(config-if-GigabitEthernet2/1)# no switchport //The configuration is not required on routers. --

### Common Errors

- BFD parameters are not set for device interfaces at one end.
- The BFD support for applications is disabled.
- The BFD support for applications is enabled only at one end.

### 6.4.2 Configuring BFD Protection

#### Configuration Effect

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD session flaps accordingly, the BFD protection can be enabled to provide protection.

#### Notes

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.
- This function and limitations are applicable only to switches.

#### Configuration Steps

##### ▾ Enabling BFD Protection

- Optional.
- Configure this function in global configuration mode on switches or routers.
- The BFD protection function raises the processing priority of BFD packets and ensures normal running of BFD services in a scenario in which devices are attacked.

<b>Command</b>	<code>bfd cpp</code>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The BFD protection function is enabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Enable the BFD protection function to provide protection if a device encounters BFD flapping due to attacks.

#### Verification

Run the **show running-config** command to verify the configuration on an interface.

#### Configuration Example

##### ▾ Enabling BFD Protection

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure this function on a switch on a network where attacks exist.</li> <li>● Configure the BFD protection function.</li> </ul>
	<pre>FS#configure terminal FS(config)# bfd cpp FS(config)# end</pre>
<b>Verification</b>	N/A

### 6.4.3 Configuring BFD Flapping Dampening

#### Configuration Effect

- ABFD session may frequently switch over between Down and Up due to link instability. As a result, a relevant application (such as static routing) may frequently switch forwarding paths and the running services are affected.
- Users can set the delay for status change advertisement, after which BFD notifies an associated application of BFD Up. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies it of BFD Down. The purpose is to reduce flapping of associated protocols caused by instable links.

#### Notes

- The BFD basic functions must be configured.
- If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

#### Configuration Steps

##### ▾ Configuring BFD Flapping Dampening

- (Optional) The BFD flapping dampening is disabled on ports by default. If a BFD session frequently switches over between Down and Up, it is advised to enable this function.
- Configure this function on ports of switches or routers.
- With BFD flapping dampening enabled, it is relieved that associated applications, such as route re-calculation, process quantities of advertisements because of frequent status BFD change. The larger the configured time is, the longer the required BFD stability time is. BFD notifies an application module of BFD Up only after the stability time reaches the configured time.

<b>Command</b>	<b>bfd up-dampening</b> [ <i>milliseconds</i> ]
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the delay for status change advertisement, after which BFD notifies an associated application of BFD Up, with the unit of milliseconds. The value ranges from 0 to 300,000. The value 0 indicates that BFD notifies the application layer immediately when a session switches over from Down to Up and the default value is 0.
<b>Defaults</b>	The BFD flapping dampening function is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This function needs to be enabled only when the link is instable. If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

#### Verification

Run the **show running-config** command to verify the configuration on an interface.

## Configuration Example

### Configuring BFD Flapping Dampening with the Advertisement Delay as 60,000 Milliseconds

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure this function in an environment where BFD frequent flaps due to link instability.</li> <li>Set the delay for status change advertisement to 60,000 milliseconds.</li> </ul>
	<pre>FS#configure terminal FS(config)# interface fastEthernet 0/2 FS(config)# bfd up-dampening 60000 FS(config)# end</pre>
<b>Verification</b>	N/A

## 6.5 Monitoring

### Displaying

Description	Command
Displays BFD session information.	<b>show bfd neighbors</b> [ <i>vrf vrf-name</i> ][ <i>client</i> { <i>ap</i>   <i>bgp</i>   <i>ospf</i>   <i>rip</i>   <i>vrrp</i>   <i>static-route</i>   <i>pbr</i>   <i>vrrp-balance</i>   <i>ldp-lsp</i>   <i>static-lsp</i>   <i>backward-lsp-with-ip</i>   <i>pst</i> }][ <i>ipv4 ip-address</i>   <i>ipv6 ip-address</i> ][ <i>details</i> ]

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs BFD events.	<b>debug bfd event</b> [ <i>interface interface-type interface-number</i>   <i>ipv4 ip-address</i>   <i>ipv6 ip-address</i> ]
Debugs BFD packets.	<b>debug bfd packet</b> [ <i>interface interface-type interface-number</i>   <i>ipv4 ip-address</i>   <i>ipv6 ip-address</i> ]

## 7 Configuring IP Event Dampening

### 7.1 Overview

When the Layer-3 port on a Layer-3 device frequently goes Up and Down due to manual enabling/disabling or other external causes, the routing table on the device will flap repeatedly. If a routing protocol is configured, the protocol may propagate the flap to the entire network, causing repeated updates and recalculation of neighboring routes, which wastes network bandwidths and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, which affects the normal running of customer networks.

IPEventDampening detects abnormal Up/Down flapping and automatically suppresses frequent port state changes, which prevents the propagation of single-point link failures by a routing protocol. When

the port is restored, it will be automatically unsuppressed, thus reducing network flaps and CPU resource consumption while improving network stability.

### Protocols and Standards

- RFC2439: BGP Route Flap Dampening

**i** At its core, the suppression algorithm used by IP Event Dampening is the same as that used by BGP Route Flap Dampening.

## 7.2 Applications

Application	Description
Routed Port Flap Dampening	Monitors the state change of the Layer-3 port on a router, and suppresses frequent port flapping.

### 7.2.1 Routed Port Flap Dampening

#### Scenario

In a network that runs a routing protocol, when a port on a router connected to another router frequently goes Up and Down, neighboring routes will be repeatedly updated and recalculated. The routing protocol may propagate the flap to the entire network, causing a network flap. IP Event Dampening can be enabled on the connected routers to monitor port state changes and suppress frequent port flapping, thus reducing network flaps and CPU resource consumption while improving network stability.

Figure 7-1

**Remarks** A and B are routers.

#### Deployment

Configure IP Event Dampening on port GE0/1 on Router A and port GE0/1 on Router B respectively.

The subinterfaces and the virtual templates of interfaces on routers do not support the dampening feature.

## 7.3 Features

### Basic Concepts

#### ⌵ Penalty

A port that goes Up or Down gets a penalty for each state change, but the penalty decays exponentially when the port is stable. In this way, port behaviors can be sensed and controlled intelligently.

### ✚ Suppress Threshold

When the cumulative penalty of a port exceeds a suppress threshold, the port is considered to flap and will be suppressed.

### ✚ Half-Life Period

The half-life period is the period required for the penalty to decrease to half of the original value when the port is stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the port is detected to be stable, but the flap detection sensitivity is reduced.

### ✚ Reuse Threshold

When the port no longer flaps and its penalty decays to a certain degree (below the suppress threshold), the port is considered to be stable and is unsuppressed.

### ✚ Maximum Suppress Time

When a port keeps flapping and reaches a very large penalty, the port will not be usable for a long time. To avoid this problem, the maximum suppress time is defined to always maintain the port suppression duration below a certain value no matter how long the port has flapped.

## Overview

Feature	Description
<a href="#">Port Flap Suppression</a>	Configure the criteria and parameters of flap suppression on ports to enable switches to identify and suppress frequently flapping ports, which ensures route stability and avoids route flap propagation.

## 7.3.1 PortFlapSuppression

### Working Principle

A port configured with IP Event Dampening is assigned a penalty. The port gets a penalty of 1,000 each time when it goes Down, but the penalty decreases with time. If the port goes Down again, the penalty increases accordingly. When the cumulative penalty exceeds the suppress threshold, the port will be suppressed. For the affected upper-layer protocol, the suppressed port is always Down no matter what the actual port state is. When the penalty decreases to the reuse threshold, the port will be unsuppressed, and the upper-layer protocol can sense the actual port state.

If a Layer-3 port is not configured with IP Event Dampening, or is not suppressed by it, the routing protocol or other protocol concerned about the port status still work normally. When the port is suppressed, the upper-layer protocol considers the port to be Down. Any state change of the port before the port is unsuppressed does not affect the routing table and the route calculation and advertisement performed by the upper-layer routing protocol.

### Related Configuration

#### ✚ Configuring IP Event Dampening

- By default, IP Event Dampening is disabled on Layer-3 ports.
- Run the **dampening** [*half-life-period* [*reuse-threshold* *suppress-threshold* *max-suppress* [**restart** [*restart-penalty*]]]] command to enable or disable IP Event Dampening on Layer-3 ports.

## 7.4 Configuration

Configuration	Description and Command
Enabling IP Event Dampening	 (Mandatory) It is used to suppress Layer-3 port flapping.
	<b>dampening</b> Configures IP Event Dampening.

### 7.4.1 Enabling IP Event Dampening

#### Configuration Effect

When a port configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the port is set to Down.

#### Notes

- When a Layer-3 port on a switch is converted to a Layer-2 port (for example, from a routed port to a switch port), the IP Event Dampening configuration on the port will be deleted.

#### Configuration Steps

##### ▾ Configuring IP Event Dampening

- Mandatory.
- Perform the configuration in Layer-3 interface configuration mode.
- You can specify the half-life period, reuse threshold, suppress threshold, maximum suppress time, and initial penalty. If you do not set these parameters, their default values will be used.

#### Verification

Use any one of the following commands to check whether the configuration takes effect:

- show running-config**
- show interfaces [ interface-id ] dampening**, which is used to check the IP Event Dampening configuration on a specified port

#### Related Commands

##### ▾ Enabling IP Event Dampening on a Port

<b>Command</b>	<b>dampening</b> [ <i>half-life-period</i> [ <i>reuse-threshold</i> <i>suppress-threshold</i> <i>max-suppress</i> [ <b>restart</b> [ <i>restart-penalty</i> ] ] ] ]
<b>Parameter Description</b>	<p><i>half-life-period</i>: Indicates the half-life period. Value range: &lt;1–30&gt;; default value: 5s.</p> <p><i>reuse-threshold</i>: Indicates the reuse threshold. Value range: &lt;1–20,000&gt;; default value: 1,000.</p> <p><i>suppress-threshold</i>: Indicates the suppress threshold. Value range: &lt;1–20,000&gt;; default value: 2,000.</p> <p><i>max-suppress</i>: Indicates the maximum suppress time. Value range: &lt;1–255&gt;; default value: four times the half-life period.</p> <p><b>restart</b> <i>restart-penalty</i>: Indicates the initial penalty. Value range: &lt;1–20,000&gt;; default value: 2,000.</p>
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	IP Event Dampening can affect direct routes, host routes, static routes, dynamic routes, and VRRP. When a port is suppressed based on the configured criteria, the affected modules determine that the port is Down and therefore

delete corresponding routes. No data packet will be transmitted through the port.

When the **dampening** command is rerun on a port configured with IP Event Dampening, the dampening information on the port will be cleared, but the flap count is retained, unless you use the **clear counters** command to clear the counters on the port.

If the **max-suppress** parameter is set to a very small value, making the maximum penalty smaller than the suppress threshold, the port will never be suppressed. When such a configuration error occurs, the following message indicating a configuration failure will be printed:

```
% Maximum penalty (10) is less than suppress penalty (2000). Increase maximum suppress time
```

If the available system memory is insufficient to run the **dampening** command, the following message indicating a configuration failure will be printed:

```
% No memory, configure dampening fail!
```

### Configuration Example

#### Configuring IP Event Dampening on Layer-3 Ports

<p><b>Scenario</b> Figure 7-2</p>	
<p><b>Configuration Steps</b></p>	<p>Enable IP Event Dampening on port GigabitEthernet 0/1 on Router A and on port GigabitEthernet 0/1 on Router B respectively, and set <b>half-time-period</b> to 30s, <b>reuse-threshold</b> to 1,500, <b>suppress-threshold</b> to 10,000, and <b>max-suppress</b> to 120s.</p>
<p><b>A</b></p>	<pre>FS(config)#interface GigabitEthernet 0/1 FS(config-if-GigabitEthernet 0/1)#dampening 30 1500 10000 100</pre>
<p><b>B</b></p>	<pre>FS(config)#interface GigabitEthernet 0/1 FS(config-if-GigabitEthernet 0/1)#dampening 30 1500 10000 100</pre>
<p><b>Verification</b></p>	<p>Run the <b>show interfaces dampening</b> command to check the IP Event Dampening configuration on the corresponding ports.</p>
	<pre>FS#show interfaces dampening GigabitEthernet 0/1   Flaps Penalty Supp   ReuseTmHalfL   ReuseV  SuppV   MaxSTm  MaxP   Restart   0      0      FALSE  0      30      1500   1000   100   15119  0</pre>

### Common Errors

- The port on a Layer-3 switch is not converted to a routed port by using the **no switchport** command before IP Event Dampening is configured.

## 7.5 Monitoring

### Clearing

Description	Command
Clears the interface counters.	<b>clear counters</b>

 For details about the **clear counter** command, see the related chapter for the "Interface" command.

### Displaying

Description	Command
Displays the counters on suppressed ports.	<b>show dampening interface</b>
Displays the IP Event Dampening configuration on ports.	<b>show interfaces dampening</b>

### Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables debugging of IP Event Dampening.	<b>debug dampening interface</b>

## 8 Configuring VSU(Stacking)

### 8.1 Overview

In order to improve the reliability of networks, the two devices at core layer and convergence layer of traditional networks are configured with two cores to provide redundancy. Access and convergence devices are respectively connected to the cores through two links. The following figure shows a typical traditional network architecture. Redundant network architecture increases the complexity of network design and operation. At the same time, a large number of redundant links reduce the utilization of network resources and return on investment.

Figure 8-1 Traditional network architecture

Virtual Switching Unit (VSU) or Stacking is a kind of network system virtualization technology that supports combining multiple devices into a single virtualized device. As shown in Figure 8-2, access, convergence and core layer devices can respectively form VSUs, and then these VSUs connect to one another to form an end-to-end VSU network. Compared with traditional network, this networking can:

- Simplify the network topology.
- Reduce the costs of network management and maintenance.
- Shorten application recovery time and service interruption time.
- Enhance the utilization of network resources.

Figure 8-2 End-to-End VSU Networking

## 8.2 Applications

Application	Description
<u>Managing Multiple Devices in a Unified Manner</u>	Uses multiple physical devices as a logical device for unified management.
<u>Simplifying Networking Topology</u>	Uses a VSU as a logical device to simplify the networking topology.

### 8.2.1 Managing Multiple Devices in a Unified Manner

#### Scenario

When multiple physical devices form a VSU system, the physical devices can be viewed as a logical device. All configurations are managed on the global master device.

As shown in Figure 8-3, four devices (numbered as 1, 2, 3, and 4 from left to right) form a VSU system. Device 1 is the global master device, device 2 is the global slave device, and devices 3 and 4 are the global candidate devices.

- All devices are configured simply on the global master device.

Figure 8-3

<b>Remarks</b>	<p>The devices from left to right in Figure 1-3 are Device 1, Device 2, Device 3 and Device 4.</p> <p>For details on VSL, see the description in section 1.3.1.</p> <p>Device 1 is the global master device.</p> <p>Device 2 is the global slave device.</p> <p>Devices 3 and 4 are the global candidate devices.</p>
----------------	---

#### Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.
- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when faulty.
- The global candidate devices are involved in data forwarding and do not run control-plane protocols. When the global slave device is faulty, a global candidate device can take over the work of the global slave device. In this case, when the global master and slave devices are faulty, the VSU system will restart.

### 8.2.2 Simplifying Networking Topology

#### Scenario

In traditional networks as shown in Figure 8-4, redundant devices and lines need to be added to increase the networking reliability; however, many algorithms also need to be introduced to prevent loops, which make the networking more complex. In the VSU system, all devices are viewed as a logical

device. Different devices back up each other, and no loop prevention algorithm needs to be introduced, which can simplify the network.

- Two aggregate switches form a VSU system. It is unnecessary to configure a loop prevention algorithm. The two switches are redundant mutually.
- The access switch is connected to the aggregate switches through the uplink AP.
- When a switch in the VSU system is faulty, the other link still works.

Figure 8-4

### Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.
- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when the global master device is faulty.
- The access switch is oriented to users and allows access by users' devices.

## 8.3 Features

### Basic Concepts

#### VSU System

VSU system is a single logical entity consisting of two or multiple devices in traditional network architecture. For example, the convergence layer VSU system as shown in the following figure can be seen as a single device that interacts with the core layer and access layer.

Figure 8-5 Convergence layer VSU

In the above VSU network structure, the member devices form a logical entity through internal links and the access layer devices are connected to the VSU through aggregated links. In this way, there is no layer 2 loop between the access and convergence layers.

Figure 8-6 Access layer VSU

Except the core and convergence layer devices, the access layer devices can also form a VSU system. A server that requires high availability can adopt multiple network cards to form an Aggregate Port (AP) to connect access layer devices. Since AP can only connect to the same access device, the risk of single device fault increases. In this case, VSU can be used to solve the problem. In the VSU mode, a server adopts multiple network cards and binds them into an AP to connect different member devices in the same VSU group. This way can prevent single point failure and network interruption caused by single link failure.

#### ➤ VSU Domain ID

A VSU domain has only one ID. Only the devices with the same domain IDs can form a VSU system.

#### ➤ Member Device ID

Every member device in a VSU system has a unique ID, namely, Switch ID. Switch IDs can be used in device management or configuring interfaces on member devices. You need to configure an ID for a device when adding the device to a VSU system and ensure that the ID is unique in the same VSU system. If an ID conflict occurs, the VSU system will reserve one device according to priority.

#### ➤ Member Device Role

A VSU system consists of several devices. When establishing a VSU system, you need to select a global master device and a global slave device. All other devices are global candidate devices. A global master device is elected from multiple devices based on an election protocol. All other devices are global slave devices in the 1: N hot standby mode. When the 1:1 hot standby mode is supported, one device is the global master device, one device is the global slave device, and all other devices are global candidate devices.

The global master device is responsible for controlling the entire VSU system, running control plane protocols and participating in data forwarding. Other devices, including the global slave devices and candidate devices, participate in data forwarding but do not run control plane protocols. All received control plane data flows are forwarded to the global master device for processing.

The global slave device also receives the statuses of the global master device in real-time and provide 1:1 or 1:N redundancy with the global master device. If the global master device becomes faulty, the global slave device will take over services from the master device and manage the entire VSU system.

- ② The following is the method for selecting the master device of a VSU system:
- Rules for selecting the master device of a VSU system include (Continue with the next rule if the previous rule does not help in selecting the master device): a) Select the currently running host as the master device with the highest priority (All devices are not master devices during startup). b) Select the device with the highest priority as the master device. c) Select the device with the lowest device No. as the host. d) Select the device with the smallest MAC address as the master device.
  - In the 1:N hot standby mode, select the device that has the most familiar configurations with the master device as the slave device to prevent dual active devices. The selection order is: the nearest/the highest priority/the smallest MAC address.
  - VSU system supports hot adding a support device. Even the hot added device has a higher priority than the master device has, the VSU system does not perform active/standby switch.
  - The startup order of member device may affect the election of master device. A member device may not join in the VSU system because it starts up too slowly. In this case, the device will be hot added to the VSU system. Even the device has a higher priority than the master device, the VSU system does not perform active/standby switchover.

## Overview

Feature	Description
<u>Virtual Switching Link (VSL)</u>	In a VSU system, a virtual link is used to connect all devices.
<u>Topology</u>	Describes the internal topology of a VSU system.
<u>Dual-Active Detection (DAD)</u>	Avoids that dual master switches coexist in a VSU domain.
<u>System Management</u>	Describes possible connections between external devices and VSU devices.
<u>Quick Blinking Location</u>	Manages devices in the VSU system.

### 8.3.1 Virtual Switching Link (VSL)

#### Working Principle

##### ↘ VSL

The VSU system is a network entity that consists of multiple devices. These devices need to share control information and part of data streams. The VSL is a special link used for transmission of control information and data streams among devices of the VSU system. For example, the VSL can be established between two devices through 10 Gigabit Ethernet interfaces. Figure 8-7 shows the position of the VSL in the VSU system.

Figure 8-7 VSL

The VSL exists in the form of AP groups. The data streams transmitted through the VSL balance load among the aggregation port members according to the traffic balancing algorithm.

##### ↘ VSL Traffic

The control streams transmitted through the VSL between devices include:

1. The protocol packets received by the member devices: These protocol packets need to be forwarded through the VSL to the global master device for processing.
2. The protocol packets processed by the global master device: These protocol packets need to be forwarded through the VSL to the interfaces of other member devices and then sent to the peer devices by these interfaces.

The data streams transmitted through the VSL between devices include:

1. The data stream flooded on the VLAN
2. The data streams that need to be forwarded across devices and transmitted through the VSL

Furthermore, the internal management packets of the VSU system are also transmitted through the VSL. The management packets include the protocol information switched by the hot backup and configuration information delivered by the host to other member devices.

- ⓘ In terms of the switched port analyzer (SPAN) function, the interface associated with the VSL cannot be regarded as the source port or destination port of the SPAN.

#### ↘ VSL Failure

If a certain member link connected to the VSL AP group fails to work, the VSU will adjust the configurations of the VSL aggregation port automatically to prevent the traffic from being transmitted through the faulty member link.

If all member links are disconnected to the VSL AP group, the VSU topology will change. If the original VSU topology is a ring topology, the ring will convert into a line. For details, see topology ring and line conversion in the section of *Topology Changes*.

#### ↘ Detecting Error Frames on a VSL Interface

When a large number of consecutive error frames are detected on a VSL interface, the interface must be disabled and switched to another VSL interface. The detection method is as follows:

If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interface every 5 seconds by default. If the number of error frames is greater than the value of *num* as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for the value of *times*, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Different user scenarios have different requirements for *num* and *times*. The default value of *num* is 3 and that of *times* is 10. If users have strict requirements on the scenarios, select smaller values for *num* and *times*; if reverse, select greater values.

### 8.3.2 Topology

The VSU system supports line topology and ring topology. Devices are connected through a VSL to form a line that is called the line topology.

#### Working Principle

##### ↘ Topology

The line topology is simple. It uses a very few ports and cables. Two devices are connected with a communication link only. Therefore, the VSL has low reliability.

Figure 8-8 Line topology

Except for the line topology, devices can also form a ring topology, as shown in Figure 8-9. In the ring topology, the two communication links between devices can back up for each other and perform link redundancy to improve the reliability of the VSU system.

Figure 8-9 Ring Topology

- ? You are advised to select the ring topology for the VSU system, thus the normal operation of the whole VSU system will not be affected by any single faulty device or VSL.
- ? Besides selecting the ring topology networking, you are advised to configure multiple VSLs for every VSL member to improve the reliability of a single VSL. At least two links are recommended and a maximum of four links can be configured. A reasonable configuration comprises more than two VSLs crossing different cards.

### 📌 Topology Convergence

Before the establishment of the VSU, the member devices need to discover neighbors through topology discovery protocols and check devices in the VSU system to confirm the range of the management domain. Then a global master device is selected to manage the whole VSU system and a global slave device is selected for backup of the master device. Then the whole VSU topology is converged. As the start up time differs for different devices, the first convergence time of the topology is also different.

### 📌 Topology ring and Line Conversion

In a ring topology, if a VSL link is disconnected, the ring topology will convert into a line topology. The whole VSU system will still run normally without network disconnection. To prevent other VSL links and nodes from being faulty, you are advised to locate the VSL failures and recover the availability of the VSL. After the VSL link is recovered, the line topology will convert into the ring topology.

Figure 8-10 Ring-to-line and line-to-ring

➤ **Topology Splitting**

In the line topology, if the VSL link is disconnected, the line topology will be split, as shown in Figure 8-11. A VSU group is split into two groups. In this condition, two devices with the absolutely same configurations may exist on the network, which will cause abnormal operation of the network. Therefore, the multi-active detection (MAD) function needs to be deployed to solve the problem of topology splitting.

Figure 8-11 Topology splitting

➤ **Topology Combining**

If the two VSU groups are connected through the VSL link, the line topology will be combined. During the topology combining, restart one VSU group and then hot add the other VSU group.

The principle of topology combining: Minimizing influences on the services during topology combining. The rules are as follows (Judge from the first item. If you cannot select the optimal topology, continue to judge the next item):

- Use the device priority as the first criteria for judging topology combining. Reserve the VSU group containing a device with the highest priority.
- If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).

- If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the global master switches).

Figure 8-12 Topology combining

- Ⓜ During topology combining of two VSU groups, the two VSU groups need to be elected. The VSU group that fails the election will restart automatically and hot add to the other VSU group.

### 8.3.3 Dual-Active Detection (DAD)

#### Working Principle

When the VSL is disconnected, the slave device switches to the master device. If the original master device is still running, a series of problems including IP address conflict on the LAN will be caused due to there are two master devices and their configurations are the same completely. In this condition, the VSU system must detect the two devices and take recovery measures. The VSU system provides two methods to perform MAD as follows:

- Bidirectional forwarding detection (BFD)
- AP-based detection

#### ▾ MAD Rules

1. Select the VSU group with the highest priority.
2. If the previous item cannot help make a judgment, select the VSU group with more physical devices.
3. If the previous item cannot help make a judgment, select the VSU group with a higher health. (Health: total bandwidth of all physical interfaces (except for management and VSL interfaces) in the UP state in the topology.)
4. If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
5. If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the two global master switches).
6. If the previous item cannot help make a judgment, reserve the VSU group with a greater startup time (that of the global master switches).

#### ▾ BFD

The VSU system supports the BFD to detect multiple master devices. Figure 8-13 shows the topology. A link is added for the two devices on the edges for MAD specially. When the VSL link is disconnected

between the global master and slave devices, two master devices exist concurrently. If the BFD function is set, the two master devices will send the BFD packets to each other through the BFD link. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules and enter the recovery state to avoid network abnormality.

Figure 8-13 BFD

- ⚠ When there is a pair of BFD links, you are advised to deploy the detection links at the two ends of the topology.
- ⚠ You need to adopt the extension BFD and you cannot configure the dual-active detection port by using the existing BFD configurations and commands.

➤ **MAD**

The VSU system also supports the MAD dual-active detection mechanism. Figure 8-14 shows the topology. The VSU system and the upstream device both need to support the MAD function. When the VSL link is disconnected, two master devices exist concurrently. The two master devices respectively send the MAD packets to the member ports of the MAD-APs and then the MAD packets are forwarded to each other through the upstream device. As shown in Figure 8-14, the MAD-AP has four member ports. Each member port is connected to a different device of the VSU system. When the topology splitting occurs, the four member ports all send and receive the MAD packets. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules and enter the recovery state to avoid network abnormality.

Figure 8-14 MAD based on upstream and downstream devices

In the topology above, the upstream device must be FS device and support the MAD packet forwarding function.

**8.3.4 VSU Traffic Forwarding**

**Working Principle**

➤ **Cross-device AP Group**

An AP binds multiple physical links together to form a logical link. The VSU system supports the AP across the member devices.

As shown in Figure 8-15, two devices form a VSU group. The external access device Switch A is connected to the VSU in the form of the AP. In terms of Switch A, there is no difference between the AP in Figure 8-15 and the common AP group.

Figure 8-15 Cross-device aggregation port

## ▾ Troubleshooting

You are advised to configure the cross-device AP with the physical link between the peripheral device and each VSU device. On the one hand, the VSL bandwidth can be reserved (prioritize the AP member of the same chassis as the egress to transmitted the cross-chassis AP traffic and prevent unnecessary traffic from being transmitted through the VSL link). On the other hand, the network reliability can be improved (if a certain chassis is faulty, the member ports of normal devices can work normally).

The follows sections describe the possible faults of the cross-device AP and the consequences.

- Single link failure

If a single link of the cross-device AP is faulty but other links still work normally, the cross-device AP will reallocate the traffic for the remaining normal links.

- Link failure of all cross-device AP member ports on the global master device

If the links of all cross-device AP member ports on the global master device fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the global master device, the system will forward the data stream to the corresponding egress on the global master device through the VSL link.

The control plane protocols are still running on the global master device. Therefore, the protocol packets that enter the VSU system need to be forwarded to the global master device through the VSL link for protocol computing.

- Failure of all links of other member devices

If all links of the cross-device AP and a single device A fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the member device A, the system will forward the data stream to the corresponding egress on the member device A through the VSL.

- Global master device fault

If the global master device is faulty, the hot backup switching is performed to switch the original slave device to the master device. Meanwhile, the member ports on other member devices continue working.

The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream to normal links.

- Member device fault

If a member device is faulty, the AP member link connected to this member device is disconnected. However, other member links still work normally. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream forwarding paths to normal links.

- ▾ Traffic Balancing

In a VSU system, traffic may have multiple egresses. The AP and ECMP have their own traffic balancing algorithms, for example, using destination or source MAC addresses. For details, see the *Configuring Aggregate Port*. The local forwarding first (LFF) can be configured detailed in this configuration manual. Packets received by a device are forwarded on this device first. In this way, packets can be forwarded to other devices without using a VSL.

### 8.3.5 System Management

#### Working Principle

- ▾ Access to the Console

The master device console of VSU system manages multiple devices on the system simultaneously. The consoles of the slave and candidate devices do not support command line input. However, you can configure the VSU system on the master device for a specified member device and log in to the master device console through the serial port of the slave device. A session can be used to redirect to the master console of a device.

- ▾ Slot Naming

In terms of the chassis device, in the VSU mode, the slot is named with the device number (Switch ID). Therefore, the slot number turns from one-dimensional into two-dimensional. For example, cable clip 1/1 indicates the slot numbered 1 of the slot 1 on a member device.

- ▾ Interface Naming

In the VSU working mode, a slot number may occur in multiple devices. Therefore, the interface is named with the device number (Switch ID).

For example, interface gigabitEthernet 1/0/1 indicates the Gigabit port 1 on the slot 0 of the device whose ID is 1; interface gigabitEthernet 2/0/2 indicates the Gigabit port 2 on the slot 0 of the device whose ID is 2.

- ▾ Access to the File System

In the VSU working mode, you can access to the file system on other member devices from the master device. The detailed access method is the same to that of the local file system. The unique difference is that different URL prefixes are used.

- ▾ System Upgrade

Generally the VSU system requires version consistency of the main program version numbers of the member devices. However, there are so many member devices that it takes too much time and energy to perform upgrade one by one in the standalone mode and it is also easy to make mistakes. FS switches provide consummate system upgrade solution to help you with system upgrade by adopting the two methods as follows:

- When the VSU system is being established: the system will automatically align the main program version numbers of all member devices. Once the main program versions are discovered inconsistency, the main program of the master device will be selected to be synchronized to all member devices.
- After the VSU system is established: the main program version will be synchronized to all member devices automatically by using the file that is downloaded by the TFTP.

## ↘ SYSLOG

All member devices of the VSU system can display the SYSLOG. The SYSLOG generated by the master device is displayed on the master device console with the same format to that in the standalone mode. The SYSLOG generated by other member devices is also displayed on the master device console, but the message format is different from that in the standalone mode because the device number information is added.

For example, the SYSLOG information generated in the standalone state is "%VSU-5-DTM\_TOPO\_CVG:Node discovery done. Topology converged." The SYSLOG information generated by the member device numbered 3 is "%VSU-5-DTM\_TOPO\_CVG:(3)Node discovery done. Topology converged."

### 8.3.6 Quick Blinking Location

In a network cabling environment, the equipment room where switches are located and the operation console are often at different places. If there are many devices in the environment, network administrators cannot easily locate the locations of specific devices.

Quick blinking location provides network administrators with a method for locating devices by means of quick blinking. By enable this function for a device on the console, you can easily find the corresponding device in the equipment room.

-  When quick blinking location is enabled, the status LED cannot show original status until the quick blinking location is disabled.

### 8.3.7 Device Recovery in Recovery Mode

By default, a device in recovery mode automatically restarts and is added to the VSU topology again after the VSL link recovers.

The **no recovery auto-restart enable** command is provided to disable the automatic restart and recovery function in recovery mode. After the VSL link recovers, the administrator can enable the automatic restart and recovery function in recovery mode again or manually enter the restart command for devices in recovery mode.

-  After the automatic restart and recovery function in recovery mode is disabled, the device stays in recovery mode until the administrator enables the function again or manually resets the device.

### 8.3.8 Automatic Recovery Without Restart for a Device in Recovery Mode upon Master Device Abnormality

Figure 8-16 Automatic Recovery Without Restart in Recovery Mode

By default, a device in recovery mode does not perform any operation when the master device is abnormal. The device stays in recovery mode until the VSL link recovers.

A configuration command is provided for the administrator to enable the automatic recovery without restart function in recovery mode. In this case, a device in recovery mode can automatically become the master device without being restarted and take over services of the original master device.

- i** After the automatic recovery without restart function in recovery mode is enabled, a device in recovery mode becomes the master device when a master device abnormality is detected.

## 8.4 Configuration

Configuration		Configuration and Command	
Configuring VSU in the Standalone Mode		(Mandatory) It is used to configure VSU in the standalone mode.	
		<b>switch virtual domain</b>	Configures the domain ID.
		<b>switch</b>	Configures the switch ID.
		<b>switch priority</b>	Configures the switch priority.
		<b>vsl-port</b>	Enters the VSL interface configuration mode.
		<b>port-member interface</b>	Configures the VSL member interface.
		<b>switch convert mode virtual</b>	Changes the standalone mode to the VSU mode.
		(Optional) It is used to configure the device attributes in the VSU mode.	
		<b>switch description</b>	Configures the device description.
		<b>switch crc</b>	Configures error frame check.
Configuring VSU in the VSU Mode	Configuring VSU Attributes	(Optional) It is used to configure the device attributes in the VSU mode.	
		<b>switch domain</b>	Changes the domain ID.
		<b>switch renumber</b>	Changes the switch ID.
		<b>switch description</b>	Configures the device description.
	Configuring the VSL	(Optional) It is used to configure a VSL.	
		<b>vsl-port</b>	Enters the VSL interface configuration mode.
		<b>port-member interface</b>	Configures a VSL member interface.
	Configuring Dual-Active Detection	(Mandatory) It is used to configure DAD.	
		<b>dual-active detection</b>	Configures DAD.

Configuration		Configuration and Command		
		<b>dual-active bfd interface</b>	Configures the BFD DAD interface.	
		<b>dual-active interface</b>	Configures an AP as a DAD interface.	
		<b>dual-active exclude interface</b>	Configures an excluded interface.	
	<a href="#">Configuring Traffic Balancing</a>	 (Optional) It is used to configure traffic balancing in the VSU mode.		
		<b>switch virtual aggregateport-lff enable</b>	Configures the AP LFF mode.	
		<b>switch virtual ecmp-lff enable</b>	Configures the ECMP LFF mode.	
	<a href="#">Configuring the Device Recovery Method in Recovery Mode</a>	 (Optional) It is used to configure the device recovery in recovery mode.		
		<b>no recovery auto-restart enable</b>	Disables the automatic restart and recovery function in recovery mode.	
	<a href="#">Configuring Automatic Recovery Without Restart in Recovery Mode</a>	 (Optional) It is used to configure the automatic recovery without restart function in recovery mode.		
		<b>dual-active auto-recovery enable</b>	Enables the automatic recovery without restart function in recovery mode.	
	<a href="#">Changing the VSU Mode to the Standalone Mode</a>	 (Optional) It is used to change the VSU mode to the standalone mode.		
		<b>switch convert mode standalone</b>	Changes the VSU mode to the standalone mode.	
<a href="#">Quick Blinking Location</a>	 (Optional) It is used to quickly locate a device.			
	<b>led-blink</b>	Enables quick blinking location.		
<a href="#">Configuring the MGMT Interface</a>	 (Optional) It is used to configure a device to create one MGMT interface for each chassis or create only one MGMT interface in VSU mode.			
	<b>mgmt_mode unique</b>	Configures the system to create only one MGMT interface in VSU mode.		
	<b>no mgmt_mode</b>	Configures the system to create one MGMT interface for each chassis in VSU mode.		

### 8.4.1 Configuring VSU in the Standalone Mode

#### Configuration Effect

Start up the switch in the standalone mode to set relevant VSU parameters to establish the VSU system.

#### Configuration Steps

##### ▾ Configuring VSU Attributes

- A switch starts in the standalone mode by default. You need to set the same domain ID on the two chassis of the established VSU system. The domain ID must be unique within the local area network (LAN). Furthermore, you need to set the ID of each chassis in the VSU.
- Run the **switch virtual domain** *domain\_id* command to configure the domain ID. This command is mandatory.

- Run the **switch switch\_id** command to configure the device ID in the VSU. This command is mandatory. For devices with the same priorities in the VSU system, a device with the smallest device ID is selected as the global master device.
- Run the **switch switch\_id priority priority\_num** command to configure the device priority. This command is mandatory.
- The value ranges from 1 to 255. A larger value means a higher priority.
- Run the **switch switch\_id description switch1** command to configure the device alias. This command is optional. The default name is FS. For easy identification of devices in the network environment, this item can be selected to set the device alias.
- A maximum of 32 characters are allowed.

<b>Command</b>	<b>switch virtual domain number</b>
<b>Parameter</b>	<i>number</i> : Indicates domain ID of the VSU
<b>Description</b>	
<b>Defaults</b>	The default domain ID is 100.
<b>Command</b>	Domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	Only two devices with the same domain ID can form a VSU. The domain ID must be unique within the LAN.

<b>Command</b>	<b>switch switch_id</b>
<b>Parameter</b>	<i>switch_id</i> : indicates the switch ID in the VSU system. The value varies with products.
<b>Description</b>	
<b>Defaults</b>	The default device ID is 1.
<b>Command</b>	Domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	<p>The device ID identifies each virtual device member. In VSU mode, the interface name format changes to "switch/slot/port" from "slot/port", in which "switch" is the device ID.</p> <p>If either chassis are active or if the role of the just started chassis is uncertain and both have the same priority, the chassis with a smaller ID is elected as the active one.</p> <p>This command can be only used to modify the device ID in standalone mode. In VSU mode, run the <b>switch renumber</b> command to modify the device ID. The modified device ID takes effect only after you restart the device, regardless of in standalone mode or in VSU mode.</p>

<b>Command</b>	<b>switch switch_id priority priority_num</b>
<b>Parameter</b>	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
<b>Description</b>	<i>priority_num</i> : Indicates the switch priority, ranging from 1 to 255.
<b>Defaults</b>	The default device priority is 100.
<b>Command</b>	Domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	<p>A larger value means a higher priority. A device with the highest priority is chosen as the master device.</p> <p>You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of <i>switch_id</i>. In the standalone mode, if <i>switch_id</i> is set to 1, running the <b>switch 2 priority 200</b> command does not work. You can first set <i>switch_id</i> to 2 and then run the <b>switch 2 priority 200</b> command. In the VSU mode, <i>switch_id</i> indicates the ID of the currently running switch. If the ID does not exist,</p>

	the configuration does not take effect.
--	---

<b>Command</b>	<b>switch</b> <i>switch_id</i> <b>description</b> <i>dev-name</i>
<b>Parameter</b>	<i>switch_id</i> : Indicates the device ID.
<b>Description</b>	<i>dev-name</i> : Indicates the device description, no greater than 32 characters.
<b>Defaults</b>	N/A
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	This command is configured on a device in whether standalone or VSU mode and takes effect immediately after configuration.

### ↘ Configuring the VSL

- To establish the VSU system, you need to decide which ports are configured as the VSL member ports.
- Run the **vsl-port** command to enter the VSL interface configuration mode. This command is mandatory.
- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is mandatory.

When the device enters the VSL interface configuration mode, the VSL interface can be configured or deleted.

<b>Command</b>	<b>vsl-port</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	You can run this command in the standalone or VSU mode.

<b>Command</b>	<b>port-member interface</b> <i>interface-name</i> [ <b>copper</b>   <b>fiber</b> ]
<b>Parameter Description</b>	<i>interface-name</i> : Indicates a two-dimensional interface name, such as Tengigabitethernet 1/1 and Tengigabitethernet 1/3. <b>copper</b> : Indicates the copper interface attribute. <b>fiber</b> : Indicates the optical interface attribute.
<b>Command Mode</b>	VSL interface configuration mode
<b>Usage Guide</b>	Add a member interface of the VSL link. <i>interface-name</i> indicates the two-dimensional interface name in the standalone mode. The two-dimensional interface can be the 10 Gigabit interface or Gigabit interface. (The Gigabit interface can be an opto-copper interface. If the media type is not specified, the Gigabit copper interface is adopted by default.) For an opto-copper interface, you must specify its optical or copper interface attribute. A VSL interface for a chassis device must be a 10 Gigabit interface. You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

In the standalone mode, the VSL configurations cannot take effect immediately unless the device shifts into the VSU mode and restart.

### ✚ Configuring Error Frame Check

- Run the **switch crc errors** command to configure error frame check. This command is optional. Run this command to modify the default method for checking error frames.
- If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

<b>Command</b>	<b>switch crc errors error_num times time_num</b>
<b>Parameter Description</b>	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once. <i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
<b>Defaults</b>	The default value of <b>errors</b> is 3; the default value of <b>times</b> is 10.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. The default action for an abnormal interface is displaying a log prompt. You can set the action to disabling the interface. If the interface is disabled, you must recover it by unplugging and plugging it.

Different products have different requirements for error frame check and different processing for VSL interfaces. In version 11.0, error frame check is configurable.

### ✚ Changing the Standalone Mode to the VSU Mode

- Use the **switch convert mode virtual** command to change the standalone mode to the VSU Mode.
- In the standalone mode, the software will take the following actions after you run the **switch convert mode virtual** command.
  - Back up the global configuration file *config.text* in the standalone mode as *standalone.text* for subsequent use.
  - Clear the contents of the configuration file *config.text*.
  - Write the relevant VSU configurations to the special configuration file *config\_vsu.dat*.
- If there is a *virtual\_switch.text* file on the switch, the system will prompt you whether to overwrite the contents of the file *virtual\_switch.text* to the file *config.text* (the file *virtual\_switch.text* is a backup file for the file *config.text* when the switch shifts from the VSU mode to the standalone mode). Then you can click **Yes** or **No**. Finally the switch restarts in the VSU mode and reads VSU parameters in the file *config\_vsu.dat*.

<b>Command</b>	<b>switch convert mode virtual</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	The switch is in the standalone mode by default.

<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Change the standalone mode to the VSU mode.

**Verification**

Run the **show switch virtual config** [switch\_id] command to check the VSU configuration of the current switch in the standalone mode.

<b>Command</b>	<b>show switch virtual config</b> [ switch_id ]
<b>Parameter Description</b>	switch_id: Indicates the switch ID. After this parameter is specified, only the VSU configuration of the specified device is displayed.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Use this command to display the VSU configuration in the standalone or VSU mode.

The relevant VSU configurations are set for a single physical switch and the configurations are stored in the special configuration file config\_vsu.dat. Therefore, you can view the current VSU configurations by running the **show switch virtual config** command rather than the **show running config** command.

In the standalone mode, the VSU running information is null. When you enter commands such as show switch virtual, the system will prompt you that the switch is in the standalone mode and there is no VSU running information.

**Configuration Example**

▾ **Configuring VSU in the Standalone Mode**

<b>Scenario</b> Figure 8-16	<p>Switch 1 and Switch 2 form a VSU system. The domain ID is 100. The chassis on the left side is configured as Chassis 1, with the priority of 200, alias of Switch 1, and the VSL interfaces of 1/1 and 1/2. The chassis on the right side is configured as Chassis 2, with the priority of 100, alias of Switch 2, and the VSL interfaces of 1/1 and 1/2.</p>
<b>Configuration Steps</b>	<p>6. Perform the following configuration on the Switch 1:</p> <ul style="list-style-type: none"> <li>● Configure VSU attributes and VSL interfaces.</li> <li>● Change the standalone mode to the VSU mode.</li> </ul> <p>7. Perform the following configuration on the Switch 2:</p> <ul style="list-style-type: none"> <li>● Configure VSU attributes and VSL interfaces.</li> <li>● Change the standalone mode to the VSU mode.</li> </ul>
<b>Switch-1</b>	<pre>FS# configure terminal FS(config)# switch virtual domain 100 FS(config-vs-domain)#switch 1 FS(config-vs-domain)#switch 1 priority 200</pre>

	<pre> FS(config-vs-domain)#witch 1 description switch-1 FS(config-vs-domain)# switch crc errors 10 times 20 FS(config-vs-domain))#exit FS(config)#vsl-port FS(config-vsl-port)#port-member interface Tengigabitethernet 1/1 FS(config-vsl-port)#port-member interface Tengigabitethernet 1/2 FS(config)#exit FS#switch convert mode virtual </pre>
<b>Switch-2</b>	<pre> FS# configure terminal FS(config)# switch virtual domain 100 FS(config-vs-domain)# switch 2 FS(config-vs-domain)# switch 2 priority 100 FS(config-vs-domain)# switch 2 description switch-2 FS(config-vs-domain)# switch crc errors 10 times 20 FS(config-vs-domain))#exit FS(config)#vsl-port FS(config-vsl-port)#port-member interface Tengigabitethernet 1/1 FS(config-vsl-port)#port-member interface Tengigabitethernet 1/2 FS(config-vsl-port)#exit FS#switch convert mode virtual </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show switch virtual config</b> command to view the VSU attributes of Switch 1 and Switch 2.</li> </ul>
<b>Switch-1</b>	<pre> FS#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! </pre>

	<pre>port-member interface Tengigabitethernet 1/2 ! switch crc errors 10 times 20 !</pre>
<b>Switch-2</b>	<pre>FS#show switch virtual config switch_id: 2 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 2 switch 2 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 ! switch crc errors 10 times 20 !</pre>

### Common Errors

A VSL interface of a chassis device must be 10 Gigabit or higher.

## 8.4.2 Configuring VSU in the VSU Mode

### 8.4.2.1 Configuring VSU Attributes

#### Configuration Effect

During the VSU system running, you can modify the parameters, such as domain ID, switch ID, and priority of the master device or the slave device. However, you can only log in to the VSU master device console to modify these parameters, but cannot enter the global configuration mode from the slave device console.

#### Notes

- Among the commands above, the all configuration commands take effect only after the switch restarts except the **switch sw\_id description switch1** command that can take effect immediately.

### Configuration Steps

#### ↘ Entering the Domain Configuration Mode

- Optional.
- Run this command in the VSU mode to enter the domain configuration mode. Switches with the same domain ID form a VSU system. You can modify or configure the domain ID, switch priority, and switch ID only after entering the domain configuration mode in the VSU mode.

<b>Command</b>	<b>switch virtual domain domain_id</b>
<b>Parameter Description</b>	<i>domain_id</i> : Indicates the virtual domain ID of the VSU system.
<b>Defaults</b>	The default domain ID is 100.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

#### ↘ Changing the Domain ID

- Optional.
- To modify the value of *domain\_id* for a device, you can configure this item on the master device console of the VSU system.

<b>Command</b>	<b>switch switch_id domain new_domain_id</b>
<b>Parameter Description</b>	<i>switch_id</i> : Indicates the ID of the currently running switch in the VSU mode, ranging from 1 to 8. <i>new_domain_id</i> : Indicates the modified domain ID, ranging from 1 to 255.
<b>Defaults</b>	The default domain ID is 100.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

#### ↘ Changing the Switch ID

- Optional.
- To modify the value of *switch\_id* for a device, you can configure this item on the master device console of the VSU system.

<b>Command</b>	<b>switch switch_id renumber new_switch_id [ force ]</b>
<b>Parameter Description</b>	<i>switch_id</i> : Indicates the ID of a switch. In a VSU system, the switch ID ranges from 1 to 16 for box switches. <i>new_switch_id</i> : Indicates the modified switch ID. <b>force</b> : (Optional) Indicates whether the ID of a device needs to be forcibly modified. After this parameter is added, the VSU configuration is saved immediately and the device is restarted.
<b>Defaults</b>	N/A
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

#### ↘ Changing the Switch Priority

- Optional.
- To modify the priority of a device, you can configure this item on the master device console of the VSU system.
- A larger value means a higher priority. Select the device with the highest priority as the master device.

<b>Command</b>	<b>switch switch_id priority priority_num</b>
<b>Parameter</b>	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
<b>Description</b>	<i>priority_num</i> : Indicates the switch priority, ranging from 1 to -255 for box switches.
<b>Defaults</b>	The default priority is 100.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	<p>A larger value means a higher priority. Select the device with the highest priority as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of <b>switch_id</b>. In the standalone mode, if <b>switch_id</b> is set to <b>1</b>, running the <b>switch 2 priority 200</b> command does not work. You can first set <b>switch_id</b> to <b>2</b> and then run the <b>switch 2 priority 200</b> command. In the VSU mode, <b>switch_id</b> indicates the ID of the currently running switch. If the ID does not exist, the configuration does not take effect.</p>

#### ✚ Configuring the Device Description

- Optional.
- To configure the description for a device, you can configure this item on the master device console of the VSU system.
- Run the **switch switch\_id description switch1** command to configure the device description. A maximum of 32 characters are allowed.

<b>Command</b>	<b>switch switch_id description dev-name</b>
<b>Parameter</b>	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
<b>Description</b>	<i>dev_name</i> : Indicates the device name.
<b>Defaults</b>	N/A
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	You can run this command in the standalone or VSU mode. The configuration takes effect immediately in the VSU mode.

#### ✚ Configuring Error Frame Check

- Optional.
- Run the **switch crc errors error\_num times time\_num** command to configure the conditions for triggering error frame check.

<b>Command</b>	<b>switch crc errors error_num times time_num</b>
<b>Parameter</b>	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once.
<b>Description</b>	<i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
<b>Defaults</b>	The default value of <b>errors</b> is <b>3</b> ; the default value of <b>times</b> is <b>10</b> .
<b>Command</b>	Domain configuration mode

<b>Mode</b>	
<b>Default Level</b>	14
<b>Usage Guide</b>	N/A

**Verification**

Use the **show switch virtual [ topology | config ]** command to display the current VSU running information, topology or configuration parameters.

<b>Command</b>	<b>show switch virtual [ topology   config ]</b>
<b>Parameter</b>	<b>topology:</b> Indicates topology information.
<b>Description</b>	<b>config:</b> Indicates the VSU configurations.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	View the domain ID, and the device ID, status and role of each device.

**Configuration Example**

↘ **Configuring VSU Attributes**

<p><b>Scenario</b> Figure 8-17</p>	
	<p>Switch 1 and Switch 2 form a VSU system. Modify the chassis ID of Switch 2 to 3 and its priority to 150. Assume that Switch 1 is the global master switch and perform the configuration on the global master switch.</p>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Modify the configurations of Switch 2.</li> </ul>
<b>Switch-1</b>	<pre>FS#config FS(config)# switch virtual domain 100 FS(config-vs-domain)#switch2renumber 3 FS(config-vs-domain)# switch 2 priority 150 FS(config-vs-domain)# switch 2 description switch-3</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show switch virtual config</b> command for verification.</li> </ul>
<b>Switch-1</b>	<pre>FS#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100</pre>

```

!
switch convert mode virtual
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!

```

```

switch_id: 3 (mac: 0x1201aeda0E)
!
switch virtual domain 100
!
switch 3
switch 3 priority 150
!
switch convert mode virtual
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch 3 description switch-3
!

```

#### 8.4.2.2 Configuring the VSL

##### Configuration Effect

When switches form a VSU system or when the VSU system is running, you can shift between common interfaces and VSL interfaces. However, you can only log in to the master device console of the VSU system for modification, but cannot enter the global configuration mode from the slave device console.

##### Notes

- You can log in to the console of the VSU system by using a serial port or telnet, in order to add or delete the configurations of VSL member interfaces.
- To prevent incorrect connections in actual scenarios, the VSL AP uses dynamic negotiation. You need to configure the VSL interface pool first, and then add the VSL interface pool to the same AP after successful negotiation. Interfaces connecting to the same device are within the same AP.

## Configuration Steps

### ↘ Entering the VSL Interface Configuration mode

- Run the **vsl-port** command to enter the VSL-PORT configuration mode. This command is optional.
- When the device enters the VSL-PORT configuration mode, the VSL interface can be configured or deleted.

<b>Command</b>	<b>vsl-port</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	You can run this command in the standalone or VSU mode.

### ↘ Configuring a VSL Member Interface

- Run the **port-member interface** *interface-name* [ **copper** | **fiber** ] command to add a VSL interface. This command is optional.
- Run the **port-member interface** command to configure a VSL member interface.

<b>Command</b>	<b>port-member interface</b> <i>interface-name</i> [ <b>copper</b>   <b>fiber</b> ]
<b>Parameter Description</b>	<i>interface-name</i> : Indicates a two-dimensional interface name, such as GigabitEthernet0/1 and GigabitEthernet0/3. <b>copper</b> : Indicates the copper interface attribute. <b>fiber</b> : Indicates the optical interface attribute.
<b>Defaults</b>	N/A
<b>Command Mode</b>	VSL interface configuration mode
<b>Usage Guide</b>	You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

During the VSU system running, the configured VSL member links take effect immediately. VSL interfaces need to be configured for all devices.

For box devices, VSL interfaces can be optical and copper interfaces of Gigabit or higher.

40G one-to-four interfaces cannot be configured as VSL interfaces.

-  For a 40G port (no matter whether splitting is performed for the interface), its member interfaces (namely, four 10G interfaces) cannot be shifted to VSL member interfaces.
-  If an interface has been configured as an NLB reflex interface, this interface can be shifted to a VSL member interface only after the NLB reflex interface configuration is deleted.
-  To prevent a loop that may occur when a VSL member interface exits from the VSL AP, the system automatically sets the member interface to the shutdown state when the command is executed to make the VSL member interface exit from the VSL AP. After the VSL member interface exits from the VSL AP, you can reconnect the link and run the **no shutdown** command to enable this interface again. When you configure a VSL interface, the system will shut it down first. If the configuration fails and you want to use it as a common interface, you can run the **no shutdown** command to enable this interface again. Add a member interface number that must be a three-dimensional interface number. For example, in the VSL-PORT configuration mode, if you run the **port-member interface** *Tengigabitethernet 1/1/1* command, it indicates that you configure the global three-dimensional interface 1/1/1 as a VSL interface.

**!** If VSU topology splitting occurs when you change a VSL interface to a common interface, the VSL interface cannot be deleted. You can disconnect the physical interface first and then delete the VSL interface.

**Verification**

- Use the `show switch virtual link [ port ]` to display the current VSL link running information in the VSU mode.

<b>Command</b>	<code>show switch virtual link [ port ]</code>
<b>Parameter Description</b>	<b>port:</b> Displays the status information of the VSL member interfaces.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	N/A

**Configuration Example**

**▾ Configuring the VSL**

<b>Scenario</b> Figure 8-18	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Add interface 1/1/3 as the VSL interface for Switch 1 and delete interface 1/1/2 from the VSL interface.</li> </ul>
<b>Switch-1</b>	<pre>FS#config FS(config)# vsl-port FS(config-vsl-port)# port-member interface Tengigabitethernet 1/1/3 FS(config-vsl-port)# no port-member interface Tengigabitethernet 1/1/2</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <code>show switch virtual config</code> command to view the VSL. Assume that Switch 1 is the global master switch and run the command on the global master switch.</li> </ul>
<b>Switch-1</b>	<pre>FS#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual</pre>

<pre> ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 ! </pre>
<pre> switch_id: 3 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 3 switch 3 priority 150 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 ! switch 3 description switch-3 ! </pre>

### 8.4.2.3 Configuring Dual-Active Detection

#### Configuration Effect

Configure the relevant detection mechanism to prevent the dual-active is being generated.

#### Notes

- The DAD can be configured only in the VSU mode. You are not allowed to configure the DAD mechanism in the standalone mode.
- All DAD configurations will take effect immediately after being configured on the master or slave devices in global configuration mode by running the **show running-config** command.
- The BFD-detected configuration information can be displayed only by running the dual-active detection display command rather than the BFD display command.

#### Configuration Steps

##### 📄 Configuring the BFD DAD

- The BFD DAD requires establishing a directly connected link between two switches. The interfaces on the two ends must be physical routing interfaces. The following configuration must be performed on both chassis.
- Enter the interface configuration mode of the DAD interface and configure the DAD interface as a routing interface.
- After exiting from the interface configuration mode, run the **switch virtual domain *domain\_id*** command to enter the domain configuration mode.
- In the domain mode, run the **dual-active detection bfd** command to enable BFD. This command is optional and can be used when BFD DAD needs to be configured.
- In the domain configuration mode, run the **dual-active bfd interface *interface-name*** command to configure the BFD DAD interface. This command is optional and can be used to configure the BFD DAD interface when BFD DAD is configured.
- Delete the BFD DAD interface. If no BFD DAD interface is available, BFD detection cannot be used.

<b>Command</b>	<b>switch virtual domain <i>domain_id</i></b>
<b>Parameter Description</b>	<i>domain_id</i> : Indicates the domain ID.
<b>Defaults</b>	The default domain ID is 100.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

<b>Command</b>	<b>dual-active detection { <b>aggregateport</b>   <b>bfd</b> }</b>
<b>Parameter Description</b>	<b>aggregateport</b> : Specifies the AP detection mode. <b>bfd</b> : Specifies the BFD detection mode.
<b>Defaults</b>	The DAD is disabled.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Configure this command only in the VSU mode.

<b>Command</b>	<b>dual-active bfd interface <i>interface-name</i></b>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the interface type and ID.
<b>Defaults</b>	N/A
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	A BFD DAD interface must be a routing interface and on different switches.

The BFD detection interfaces must be directly connected physical routing ports. The two ports must be on different devices.

The interface type is not limited. The dual-active detection link is only used to transmit BFD packets with a small amount of traffic. Therefore, you are advised to adopt the Gigabit interface or 100 M interface as the dual-active detection interface.

After the layer 3 routing interface that is configured with two master devices is converted into a layer 2 switch interface (run the switchport command under this interface), the BFD dual-active detection will be cleared automatically.

You are advised to directly connect BFD detection interfaces only to the master and slave devices.

- ! When the VSU system detects dual-active conflict and brings another VSU group to the recovery state, you can resolve the problem only by rectifying the VSL fault, but not directly restoring the VSU group in the recovery state; otherwise, dual-active conflict may be caused on the network.

### ⌵ Configuring the AP-based DAD

- To configure the AP-based DAD, you must configure an aggregate port (AP) first and then specify the AP port as the DAD interface.
- Run the **port-group** *ap-num* command to add a physical member interface to the AP.
- After entering the domain configuration mode, run the **dual-active detection aggregateport** command to enable AP detection mode. This command is optional. You can run this command when AP detection needs to be configured.
- Run the **dual-active interface** *interface-name* [ **vlan** *vlan-id* ] command to configure the AP as the DAD interface. This command is optional. You can run this command to configure the AP as the DAD interface when AP detection needs to be configured. When the AP is a trunk port and the native VLAN is beyond the allowable VLAN range of the AP-based DAD interface, a detection VLAN needs to be configured for the AP-based DAD interface. The configured VLAN must be within the allowable VLAN range of the trunk port, and has been correctly created on the device.
- Run the **dadrelayenable** command to enable dual-active detection packet relay for upstream and downstream interfaces. This command is optional. You can run this command to relay DAD packets (dual-active detection packets) when AP-based DAD is configured.
- Disabling AP-based DAD will inactivate DAD.
- Delete the detected interface. If no AP-based DAD interface is available, AP-based DAD cannot be used.
- If the AP is a trunk port and VLAN limits have been configured for it, **vlan** *vlan-id* (applicable to the configured limited VLANs) must be configured and the permitted VLANs must be configured on the device. Otherwise, the AP-based DAD function is unavailable.
- The AP-based DAD packet relay is disabled by default.

<b>Command</b>	<b>dual-active detection { aggregateport   bfd }</b>
<b>Parameter</b>	<b>aggregateport</b> : Specifies the AP detection mode.
<b>Description</b>	<b>bfd</b> : Specifies the BFD detection mode.
<b>Defaults</b>	The DAD is disabled.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Configure this command only in the VSU mode.

<b>Command</b>	<b>dual-active interface</b> <i>interface-name</i>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the interface type and interface ID. An AP-based DAD interface must be specified.
<b>Defaults</b>	N/A

<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Only one AP-based DAD interface can be configured. This interface must be created before you configure an AP as a DAD interface. Subsequently configured DAD interfaces will overwrite the previous ones.

<b>Command</b>	<b>dad relay enable</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	The AP-based DAD packet relay is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can only be executed on the AP.

-  You are advised to distribute the physical interfaces that are added to the AP-based detection interface to different devices.
-  If the AP is a trunk port and VLAN limits have been configured, **vlan *vlan-id*** (applicable to configured limited VLANs) must be configured and the permitted VLANs must be configured on the device.
-  The excluded interface must be routing rather than VSL.
-  After the excluded interface is converted from a routing one into a switch interface (run the **switchport** command under this interface), the configurations of the excluded interface that is associated with this interface will be cleared automatically.

#### Verification

Use the **show switch virtual dual-active { aggregateport | bfd | summary }** to display the current DAD configuration.

<b>Command</b>	<b>show switch virtual dual-active { aggregateport   bfd   summary }</b>
<b>Parameter Description</b>	<b>aggregateport:</b> Displays DAD information on the AP. <b>bfd:</b> Displays BFD-based DAD information. <b>summary:</b> Displays DAD summary.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	N/A

#### Configuration Example

##### ↘ Configuring the BFD DAD

**Scenario**  
**Figure 8-19**

- Switch 1 and Switch 2 form a VSU (The domain ID is 1) system. The priorities of Switch 1 and Switch 2 are 200 and 150 respectively. The links between Te1/3/1 and Te1/3/2 of Switch 1 and Te2/3/1 and Te2/3/2 of Switch 2 are established respectively to form a VSL between Switch 1 and Switch 2. The G0/1, G0/2, G0/3 and G0/4 interfaces of Switch A are connected to G1/1/1 and G1/2/1 of Switch 1 and G2/1/1 and G2/2/1 of Switch 2 to form an AP group including four member links. The ID of the AP group is 1. All members of AP group 1 are Gigabit optical interfaces. G1/1/2 and G2/1/2 are routing interfaces.
- G1/1/2 and G2/1/2 are a pair of BFD DAD interfaces.

**Configuration Steps**

- Configure G1/1/2 and G2/1/2 as routing interfaces.
- Enable the BFD DAD.
- Configure G1/1/2 and G2/1/2 as BFD DAD interfaces.

Since Switch 1 and Switch 2 are in a VSU system, the preceding configuration can be performed on either Switch 1 or Switch 2. on the following example configures the functions on Switch 1.

**Switch 1**

```
FS(config)# interface GigabitEthernet 1/1/2
FS(config-if-GigabitEthernet 1/1/2)# no switchport
FS(config)# interface GigabitEthernet 2/1/2
FS(config-if-GigabitEthernet 2/1/2)# no switchport
FS(config-if)# switch virtual domain 1
FS(c config-vs-domain)# dual-active detection bfd
FS(config-vs-domain)# dual-active bfd interface GigabitEthernet 1/1/2
FS(config-vs-domain)# dual-active bfd interface GigabitEthernet 2/1/2
```

**Switch A**

```
FS# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
FS(config)# interface aggregateport 1
FS(config-if-aggregateport 1)# interface range GigabitEthernet 0/1-4
FS(config-if-aggregateport 1)# port-group 1
FS(config)# interface vlan 1
```

	<pre>FS(config-if-vlan 1)#ip address 1.1.1.2 255.255.255.0 FS(config-if-vlan 1)#exit FS(config)#interface aggregateport 1 FS(config-if-AggregatePort 1)# dad relay enable FS(config-if-AggregatePort 1)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● View the DAD configuration.</li> <li>● View the BFD DAD configuration.</li> </ul>
<b>Switch 1</b>	<pre>FS# show switch virtual dual-active summary BFD dual-active detection enabled: No Aggregateport dual-active detection enabled: Yes Interfaces excluded from shutdown in recovery mode: In dual-active recovery mode: NO FS# show switch virtual dual-active bfd BFD dual-active detection enabled: Yes BFD dual-active interface configured:     GigabitEthernet 1/1/2: UP     GigabitEthernet 2/1/2: UP</pre>

### Common Errors

- A BFD DAD interface is not a routing interface.
- Neither BFD DAD nor AP-based DAD are enabled and activated.

### 8.4.2.4 Configuring Traffic Balancing

#### Configuration Effect

In the VSU system, if egresses are distributed on multiple devices, the Local Forward First (LFF) can be configured.

#### Notes

The default configuration is LFF.

#### Configuration Steps

##### ▾ Configuring the AP LFF mode

- In the domain configuration mode, run the **switch virtual aggregateport-lff enable** command to enable the AP LFF mode. This command is optional.
- The member ports of AP can be distributed on two chassis of the VSU system. You can configure whether the AP egress traffic is forwarded through local member ports first based on actual traffic conditions.

- If this function is disabled, traffic is forwarded based on the AP configuration rules. For details, see the *Configuring Aggregate Port*.

<b>Command</b>	<b>switch virtual aggregateport-lff enable</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	This function is enabled by default.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Enable the AP LFF in the VSU mode.

### ↘ Configuring the ECMP LFF mode

- In the domain configuration mode, run the **switch virtual ecmp-lff enable** command to enable the ECMP LFF mode. This command is optional.
- The Equal-Cost MultiPath (ECMP) routing egress can be distributed on two chassis of the VSU system. You can configure whether the ECMP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the ECMP configuration rules. For details, see the *Configuring Aggregate Port*.

<b>Command</b>	<b>switch virtual ecmp-lff enable</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	This function is enabled by default.
<b>Command Mode</b>	Domain configuration mode
<b>Usage Guide</b>	Enable the ECMP LFF in the VSU mode.

 In the VSU mode, the across-chassis AP LFF mode and the ECMP LFF mode are disabled by default.

 To deploy a VSU system for layer-3 switches, you are advised to configure the IP-based AP load balancing (src-ip, dst-ip and src-dst-ip).

### Verification

Use the **show switch virtual balance** command to display the current traffic balancing mode of the VSU system.

<b>Command</b>	<b>show switch virtual balance</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Use this command to display the configuration of the traffic balancing mode in the VSU mode.

### Configuration Example

#### ↘ Configuring the LFF

<p><b>Scenario</b> Figure 8-20</p>	
	<p>In Figure 1-20, Switch 1 and Switch 2 form a VSU system. It is assumed that Switch 1 is the global master switch and configuration is performed on Switch 1.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>Configure the AP LFF.</li> </ul>
<p><b>Switch-1</b></p>	<pre>FS#config FS(config)# switch virtual domain 100 FS(config-vs-domain)# switch virtual aggregateport-lff enable</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>Run the <b>show switch virtual balance</b> command for verification.</li> </ul>
<p><b>Switch-1</b></p>	<pre>FS#show switch virtual balance Aggregate port LFF: enable Ecmp lff enable</pre>

#### 8.4.2.5 Changing the VSU Mode to the Standalone Mode

##### Configuration Effect

Dismiss the VSU system into individual devices that can operate in the standalone mode.

##### Configuration Steps

- Run the **switch convert mode standalone** [*switch\_id*] command to change the VSU mode to the standalone mode. This command is optional.
- After you run this command, the system will prompt you as follows: Whether to restore the configuration file to standalone text? If **yes**, the configuration file will be restored; if **no**, the configuration of virtual device mode will be cleared.

<p><b>Command</b></p>	<p><b>switch convert mode standalone</b> [<i>switch_id</i>]</p>
<p><b>Parameter Description</b></p>	<p><i>switch_id</i>: Indicates the switch ID.</p>
<p><b>Defaults</b></p>	<p>The switch is in the standalone mode by default.</p>
<p><b>Command Mode</b></p>	<p>Privileged EXEC mode</p>
<p><b>Usage Guide</b></p>	<p>After you run the <b>switch convert mode standalone</b> command, the master switch backs up the global configuration files of all VSDs in the VSU mode as <i>vsd.virtual_switch.text.vsd ID</i>. Then, the master switch clears the global configuration files <i>config.text</i> of all VSDs in the VSU mode, and asks you whether to overwrite the global configuration files <i>config.text</i> with <i>vsd.standalone.text.vsd ID</i>. If you select <b>yes</b>, the content of <i>vsd.standalone.text.vsd ID</i> will overwrite the global configuration file <i>config.text</i> of all VSDs; otherwise, the master switch does not recover <i>config.text</i>. Finally, restart the switch.</p>

This command can be used in the standalone mode or VSU mode. If the command is executed in the standalone mode, the mode switching is performed on the current switch. If the command contains the *sw\_id* parameter and is executed in the VSU mode, the mode switching is performed on the switch with the ID specified by *sw\_id*. If the command does not contain the *sw\_id* parameter, the mode switching is performed on the master switch. You are advised to switch the mode of the slave switch and then that of the master switch.

**Configuration Example**

📌 **Changing the VSU Mode to the Standalone Mode**

<p><b>Scenario</b> Figure 8-21</p>	 <p>In Figure 8-21, it is assumed that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master switch.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Change the mode of Switch 1 to the standalone mode.</li> <li>● Change the mode of Switch 2 to the standalone mode.</li> </ul>
<p><b>Switch-1</b></p>	<pre>FS# switch convert mode standalone 1 FS# switch convert mode standalone 2</pre>
<p><b>Verification</b></p>	<p>Run the <b>show switch virtual config</b> command to display the switch status.</p>
<p><b>Switch-1</b></p>	<pre>FS#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode standalone ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>
	<pre>switch_id: 2 (mac: 0x1201aeda0E) !</pre>

```

switch virtual domain 100
!
switch 2
switch 2 priority 150
!
switch convert mode standalone
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch 2 description switch-2
!

```

### 8.4.3 Configuring Quick Blinking Location

#### Configuration Effect

- Enable quick blinking location of a switch to make the status LED of the switch quickly blink.

#### Notes

If you do not disable quick blinking location, the system automatically disables the function 30 minutes after it is enabled.

#### Configuration Steps

##### ✎ Enabling/Disabling quick blinking location

- Mandatory. Use this function on a switch that needs to be located.
- In the privileged EXEC mode, run the **led-blink** command to enable quick blinking location.

<b>Command</b>	<b>led-blink { enable   disable } [ device <i>device_id</i> ]</b>
<b>Parameter Description</b>	<b>enable:</b> Enables quick blinking location. <b>disable:</b> Disables quick blinking location. <i>device_id:</i> Indicates the device ID.
<b>Defaults</b>	Quick blinking location is disabled by default.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Run this command without the <i>device_id</i> parameter to enable or disable the quick blinking search in the standalone mode. In the VSU mode, you can set the <i>device_id</i> parameter to enable or disable this function for a specified device. If you ignore the <b>device_id</b> parameter, you can enable or disable this function for all devices in the VSU system. If you do not disable this function, the system automatically disables the function 30 minutes after it is enabled.

	This configuration cannot be saved. Quick blinking location will be disabled upon restart or failover.
--	--

#### Verification

- Check whether the status LED of a switch quickly blinks.

#### Configuration Example

##### ▾ Enabling quick blinking location for the two VSU devices

<b>Scenario</b>	Assume that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master device.
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enter the <b>led-blink enable device 2</b> command on the Switch 1 console to enable quick blinking location.</li> <li>● Enter the <b>led-blink enable device 2</b> command on the Switch 1 console to disable quick blinking location.</li> </ul>
<b>Verification</b>	When quick blinking location is enabled, check whether the status LED of Switch 2 quickly blinks.

#### 8.4.4 Configuring the MGMT Interface

##### Configuration Effect

- Configure a device to create one MGMT interface for each chassis or create only one MGMT interface for the system in VSU mode.

##### Notes

After this command is configured, run the **write** command to save the configuration. The configuration takes effect only in VSU mode and only after the device is restarted.

##### Configuration Steps

##### ▾ Configuring a Device to Create Only One MGMT Interface for the System in VSU Mode

- Optional. Configure this function only when a device needs to create only one MGMT interface for the system. One MGMT interface is created for each chassis by default.
- In global configuration mode, run the **mgmt\_mode** command to configure the MGMT interface.

<b>Command</b>	<b>mgmt_mode unique</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	In VSU mode, set the system to create only one MGMT interface. The configuration needs to be saved, and takes effect only after the device is restarted.

##### ▾ Configuring a Device to Create One MGMT Interface for Each Chassis

- Optional. After a device has been configured to create only one MGMT interface, use this command to restore default configuration, that is, to create one MGMT interface for each chassis.

<b>Command</b>	<b>no mgmt_mode</b>
----------------	---------------------

<b>Parameter Description</b>	N/A
<b>Defaults</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	In VSU mode, set the system to create one MGMT interface for each chassis. The configuration needs to be saved, and takes effect only after the device is restarted.

**Verification**

After configuration, run the **write** command to save the configuration. After running the **reload** command to restart the device, run the **show interface** command to display the number of MGMT interfaces.

**Configuration Example**

▾ **Configuring a Device to Create Only One MGMT Interface for the System in VSU Mode**

<p><b>Scenario</b> Figure 1- 22</p>	 <p>Switch-1 Chassis 1 Priority 100</p> <p>Switch-2 Chassis 2 Priority 100</p> <p>Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>Run the command to configure a device to create only one MGMT interface for the system, run the <b>write</b> command to save the configuration, and run the <b>reload</b> command to restart the device for the configuration to take effect.</li> </ul>
	<pre>FS(config)#mgmt_mode unique Please write and reload system to take config effect! FS(config)#exit FS#write  Building configuration...  [OK] FS#reload Reload system?(Y/N)y</pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>After the device is restarted, run the <b>show interfaces   inc mgmt</b> command. The system creates only one MGMT interface even if there are multiple chassis in the VSU mode.</li> </ul> <pre>FS#show interfaces   inc Mgmt ===== Mgmt 0 ===== Mgmt 0 is UP , line protocol is UP Hardware is Mgmt, address is 1414.3344.5519 (bia 1414.3344.5519)</pre>

### 8.4.5 Configuring the Device Recovery in Recovery Mode

#### Configuration Effect

Disable the automatic restart and recovery function in recovery mode.

#### Notes

If the automatic restart and recovery function is disabled, the function needs to be enabled again or the devices need to be manually restart for devices in recovery mode.

#### Configuration Steps

##### ▾ Enabling/Disabling the Automatic Restart Function in Recovery Mode

- Mandatory. Enable or disable the function on a device as required.
- In config-vs-domain configuration mode, run the **[no] recovery auto-restart enable** command to enable or disable automatic restart function.

<b>Command</b>	<b>recovery auto-restart enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The automatic restart and recovery function in recovery mode is enabled by default.
<b>Command Mode</b>	config-vs-domain configuration mode
<b>Usage Guide</b>	This command can be executed only in VSU mode. After the command is configured, the configuration needs to be saved for the configuration to take effect immediately.

#### Verification

Run the **show run** command to display the configurations.

#### Configuration Example

##### ▾ Disabling Automatic Restart and Recovery in Recovery Mode in VSU Mode

<b>Scenario</b>	Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device. The dual-active detection function is enabled.
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Run the <b>switch virtual domain 100</b> command on Switch-1 to enter the config-vs-domain configuration mode.</li> <li>● Run the <b>no recovery auto-restart enable</b> command on Switch-1 to disable the automatic restart and recovery function.</li> </ul>
<b>Verification</b>	<p>Disconnect the VSL link. After dual-active detection is completed, Switch-2 enters the recovery mode.</p> <p>Re-connect the VSL link. Switch-2 does not restart.</p> <p>Run the <b>recovery auto-restart enable</b> command on Switch-2 to enable the automatic restart and recovery function.</p> <p>Switch-2 automatically resets.</p>

### 8.4.6 Configuring Automatic Recovery Without Restart in Recovery Mode

#### Configuration Effect

Enable the automatic recovery without restart function in recovery mode.

### Configuration Steps

#### ▾ Enabling/Disabling the Automatic Recovery Without Restart Function in Recovery Mode

- Mandatory. Enable or disable the function on a device as required.
- In config-vs-domain configuration mode, run the **[no] dual-active auto-recovery enable** command to enable or disable the automatic recovery without restart function.

<b>Command</b>	<b>dual-active auto-recovery enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The automatic recovery without restart function in recovery mode is disabled by default.
<b>Command Mode</b>	config-vs-domain configuration mode
<b>Usage Guide</b>	This command can be executed only in VSU mode. After the command is configured, the configuration needs to be saved for immediate validation.

### Verification

Run the **show run** command to display the configurations.

### Configuration Example

#### ▾ Enabling Automatic Recovery Without Restart in Recovery Mode in VSU Mode

<b>Scenario</b> Figure 1- 23	 <p>Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device. The DAD function is enabled.</p>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Run the <b>switch virtual domain 100</b> command on Switch-1 to enter the config-vs-domain configuration mode.</li> <li>● Ru the <b>dual-active auto-recovery enable</b> command on Switch-1 to enable the automatic recovery without restart function in recovery mode.</li> </ul>
<b>Verification</b>	<p>Disconnect all VSL links. After DAD is completed, Switch-2 enters the recovery mode.</p> <p>Power off Switch-1. Verify that Switch-2 automatically becomes the master device without restart.</p>

## 8.5 Monitoring and Maintenance

### Displaying

Description	Command
Displays the current VSU operation, topology or configuration.	<b>show switch virtual [ topology   config   role ]</b>

Displays the current dual-active configuration.	<code>show switch virtual dual-active { bfd   aggregateport   summary }</code>
Displays the current VSL running information in the VSU mode.	<code>show switch virtual link [ port ]</code>
Redirects to the console of the master switch or any switch.	<code>session { device switch_id   master }</code>
Displays the current switch ID.	<code>show switch id</code>

## 9 Configuring RNS

### 9.1 Overview

The reliable network service (RNS) tests specific services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. Using the RNS test results, you can:

- Learn the network performance in time and take measures accordingly to handle related network performance problems.
- Diagnose and locate network faults.

### 9.2 Applications

#### 9.2.1 Testing and Evaluating Service Performance

##### Scenario

As shown in the following figure, a company is going to deploy a video conference system between the headquarters and branches, and has completed the related quality of service (QoS) configurations. Before formal deployment, it must be checked whether the services can be provisioned normally under the existing service pressure of the company. The video conference system is sensitive to the User Datagram Protocol (UDP) delay and UDP transmission jitter of the network. The traditional ping tool can test the Internet Control Message Protocol (ICMP) performance, but cannot effectively evaluate the UDP transmission performance and cannot meet the requirement for jitter measurement.

<b>Remarks</b>	A, B, and C are switches.
----------------	---------------------------

##### Deployment

- Configure RNS on the egress switching device or switch of each branch to test the UDP jitter and delay.
- On Switch A, specify the IP address and UDP port of the egress switching device or switch in the headquarters, and then UDP packets can be automatically sent. Based on the configurations, the egress switching device or switch in the headquarters can automatically respond to the UDP packets. The egress switching device or switch of the branch processes the sent and received packets, and calculates the UDP jitter. To learn the performance in different periods of time, you also need to configure scheduling functions, such as periodically start/stop and repeated running, for the RNS.

## 9.2.2 Locating Network Faults

### Scenario

On the campus network as shown in Figure 9-1, Student 1 reports a Web server access failure, Student 3 reports an Internet access failure, and Student 6 reports an email sending/receiving failure.

Figure 9-1

### Deployment

- The administrator directly enables the DNS function on the access switch of the dormitories to test whether the domain name service (DNS) server is faulty. If DNS fails, an ICMP echo packet is automatically triggered to test whether the Web server is reachable.
- When a fault occurs, the administrator only needs to start a test, and the subsequent tests can be automatically triggered. Then, the administrator can check the test results to locate the fault, which greatly reduces the workload for the administrator.

## 9.3 Features

### Basic Concepts

#### ▾ RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure the RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

Feature	Description
<a href="#">RNS Instance</a>	Use an RNS instance to conduct a functional test.
<a href="#">Track Support for the RNS</a>	Track the test results and notify the related module of the results.

### 9.3.1 RNS Instance

Use an RNS instance to conduct a functional test, for example, testing whether the DNS function of the device is normal. Currently, the RNS supports the following types of tests: ICMP echo and DNS.

#### Working Principle

##### 📌 ICMP Echo Test

ICMP echo is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

The RNS client sends an ICMP echo request to the destination IP address based on the preset test time and frequency. On receiving the ICMP echo request, the destination address responds with an ICMP echo reply. Based on the information related to the received ICMP echo reply, for example, the packet receiving time and number of packets, the RNS client calculates the response time and packet loss rate of the destination IP address to reflect the current network performance and network status. The ICMP echo test results and historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

The precondition of a successful ICMP echo test is that the destination device can correctly respond to the ICMP echo request.

##### 📌 DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

##### 📌 Procedure for Configuring an RNS Instance Test

1. Create a test group, and configure the test parameters based on the test type.
2. Start an RNS test.
3. Use the RNS client to construct a packet of the specified test type, and send the packet to the peer end.
4. On receiving the test packet, the peer end returns a reply packet containing the timestamp.

5. The RNS client calculates the packet loss rate and round-trip time based on availability of the received reply packet and the timestamp in the reply packet.
  6. Use the show or debug command to check the test result.
- i** The preceding configuration procedure is a general test procedure of an RNS instance. For details about the specific configuration procedures for the three types of tests, see the configuration descriptions provided later.

## Related Configuration

### ▾ Configuring the Test Repeat Interval

By default, the test repeat interval is 60s.

Run the **frequency** *millisecond* command to configure the repeat interval of an instance.

Perform this configuration in IP RNS configuration mode to perform the test periodically. You can run the **frequency** command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test:

$$(\text{frequency } \textit{milliseconds}) > (\text{timeout } \textit{milliseconds}) \geq (\text{threshold } \textit{milliseconds})$$

### ▾ Configuring the Test Timeout

The default timeout varies according to the test type. You can run the **show ip rns configuration** command to display the timeout of a specific test type.

Run the **timeout** *milliseconds* command to configure the timeout of an instance.

Perform this configuration in IP RNS configuration mode. The value of **timeout** must be equal to or greater than the value of **threshold**. For the relationship between **timeout**, **frequency**, and **threshold**, see "Usage Guide" of the **frequency** command.

### ▾ Configuring the Test Threshold

By default, the test threshold is 5,000 ms.

Run the **threshold** *milliseconds* command to configure the threshold of an instance.

Perform this configuration in IP RNS configuration mode. The value of **threshold** must be equal to or smaller than the value of **timeout**. For the relationship between **timeout**, **frequency**, and **threshold**, see "Usage Guide" of the **frequency** command.

### ▾ Configuring a Tag for the Test

No default configuration is available.

Run the **tag** *text* command to configure a test tag.

Perform this configuration in IP RNS configuration mode. The **tag** command can specify a tag for a test, which is generally used to identify the function of this test.

### ▾ Configuring the Protocol Payload Size

The default protocol payload size varies according to the test type. By default, the protocol payload size of a test type is the minimum or appropriate size for the test.

Run the **request-data-size** *bytes* command to configure the protocol payload size.

Perform this configuration in IP RNS configuration mode.

#### ✚ **Configuring the TOS of the Test Packet**

By default, the TOS is 0.

Run the **tos** number command to configure the TOS field in the IPv4 packet used for the IP RNS test.

Perform this configuration in IP RNS configuration mode.

#### ✚ **Configuring the VRF**

No default configuration is available.

Run the **vrf vrf-name** command to configure the virtual routing and forwarding (VRF) of the IP RNS test.

Perform this configuration in IP RNS configuration mode.

### 9.3.2 Track Support for the RNS

Objects that can be tracked include: test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of the related module (such as DNS) is triggered.

#### Working Principle

The test result of an RNS instance is tracked as follows:

- Configure a track object for tracking the test result of an RNS instance.
- When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.
- On receiving this message, the track module locates the track object based on the RNS instance ID. After the preset delay time elapses, if the status of the RNS instance still changes, the status of the track module is modified, and the module of the track object is notified of the modification. If the status of the RNS instance recovers within the preset delay time, the track status is not modified and the related module is not notified.

#### Related Configuration

##### ✚ **Configuring a Track Object for Tracking the Link Status of An Interface**

By default, the function of tracking the link status of an interface is disabled.

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

If the link status of the interface is UP, the status of the track object is UP. If the link status of the interface is DOWN, the status of the track object is also DOWN.

##### ✚ **Configuring a Track Object for Tracking the Test Result of an RNS Instance**

By default, the function of tracking the test result of an RNS instance is disabled.

Run the **track rns** command to configure a track object, which is used to track the test result of an RNS instance. The RNS instance ID ranges from 1 to 500.

If the test result of the RNS instance is successful, the status of the track object is UP. If the test result of the RNS instance is unsuccessful, the status of the track object is also DOWN.

### ▾ Configuring a Track Object for Tracking the Test Result of an RNS List

By default, the function of tracking the test result of an RNS list is disabled.

Run the **track rns-list** command to configure a track object, which is used to track the test result of an RNS list. The RNS instance ID ranges from 1 to 500.

The result can be the AND or OR operation result of all member status. If the result of this track object is set to the OR operation result of all member status, and the OR result of the status of all the tracked RNS objects is UP, the status of this track object is UP. If the OR result of the status of all the tracked RNS objects is DOWN, the status of this track object is also DOWN. If the result of this track object is set to the AND operation result of all member status, and the AND result of the status of all the tracked RNS objects is UP, the status of this track object is UP. If the AND result of the status of all the tracked RNS objects is DOWN, the status of this track object is also DOWN.

### ▾ Configuring a Track Object for Tracking the Status of a Track List

By default, the function of tracking the status of a track list is disabled.

Run the **track list** command to configure a track object, which is used to track the status of a track list.

The result can be the AND or OR operation result of all member status.

If the result of this track object is set to the OR operation result of all member status, and the OR result of the status of all members is UP, the status of this track object is UP. If the OR result of the status of all members is DOWN, the status of this track object is also DOWN. If the result of this track object is set to the AND operation result of all member status, and the AND result of the status of all members is UP, the status of the track object is UP. If the AND result of the status of all members is DOWN, the status of this track object is also DOWN.

### ▾ Configuring a Track List Member

By default, no member is configured for the track list.

Run the **object** command to configure a track list member. The status of a track list member meeting conditions can be set to UP or DOWN.

Assume that the status of a member meeting conditions is set to UP. If the status of a track list member is UP, the member meets conditions. If the status of a track list member is DOWN, the member does not meet conditions.

### ▾ Adjusting the Delay for Notifying the Status Change of a Track Object

By default, the delay for notifying the status change of a track object is 0.

Run the **delay** command to adjust the delay for track notification, including the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. The delay ranges from 0 to 180. The unit is second.

A longer delay indicates that it takes more time before the module that is concerned with the track object is notified of the status. A shorter delay indicates that it takes less time before the module that is concerned with the track object is notified of the status.

## 9.4 Configuration

Configuration Item	Description and Command
<u>Configuring RNS Basic Functions</u>	 (Mandatory) It is used to configure basic function parameters of the RNS.
	<b>ip rns</b> <ul style="list-style-type: none"> <li>Supports detailed configuration and brief configuration.               <ul style="list-style-type: none"> <li>Detailed configuration: An IP RNS operation object is defined, and used as the configuration ID for subsequent tests and parameters.</li> <li>Brief configuration: Subsequent configuration of the testtype is not required. Currently, one-step startup of the ICMP, DNS, and TCP connect tests is supported.</li> </ul> </li> </ul>
	<b>ip rns reaction-configuration</b> <ul style="list-style-type: none"> <li>Configures the proactive threshold monitoring and triggering mechanism of the IP RNS test.</li> </ul>
	<b>ip rns reaction-trigger</b> <ul style="list-style-type: none"> <li>Triggers another type of the IP RNS test in pending state when the monitoring threshold exceeds the expectation during an IP RNS test.</li> </ul>
	<b>ip rns schedule</b> <ul style="list-style-type: none"> <li>Configures the scheduling method, start time, and life time of an IP RNS test.</li> </ul>
	<b>ip rns restart</b> <ul style="list-style-type: none"> <li>Restarts an IP RNS test.</li> </ul>
<b>ip rns reset</b> <ul style="list-style-type: none"> <li>Clears all the IP RNS configurations.</li> </ul>	
<u>Configuring the ICMP Echo Test</u>	 (Optional) It is used to implement the ICMP echo test.
	<b>icmp-echo</b> <ul style="list-style-type: none"> <li>Creates an RNS test, the type of which is ICMP echo.</li> </ul>
	<b>request-data-size</b> <ul style="list-style-type: none"> <li>Configures the protocol payload size.</li> </ul>
	<b>frequency</b> <ul style="list-style-type: none"> <li>Configures the test repeat interval.</li> </ul>
	<b>tag</b> <ul style="list-style-type: none"> <li>Configures a tag.</li> </ul>
	<b>threshold</b> <ul style="list-style-type: none"> <li>Configures the test threshold.</li> </ul>
	<b>timeout</b> <ul style="list-style-type: none"> <li>Configures the test timeout.</li> </ul>

	<b>timeout</b> <ul style="list-style-type: none"> <li>Configures the test timeout.</li> </ul>
	<b>tos</b> <ul style="list-style-type: none"> <li>Configures the TOS field in the header of the IPv4 test packet.</li> </ul>
<b>vrf</b> <ul style="list-style-type: none"> <li>Configure the VRF of a test.</li> </ul>	
<u>Configuring the Track Support for the RNS</u>	 (Optional) It is used to configure the track support for other test modules.
	<b>track rns</b> <ul style="list-style-type: none"> <li>Configures a track object for tracking the test result of an RNS instance.</li> </ul>

Configuration Item	Description and Command	
	<b>track interface line-protocol</b>	Configures a track object for tracking the link status of an interface.
	<b>track list</b>	Configures a track object for tracking the status of a track list.
	<b>object</b>	Configures a member object for a track list object.
	<b>delay</b>	Configures the delay for notifying the status change of a track object.

### 9.4.1 Configuring RNS Basic Functions

#### Configuration Effect

- Detailed configuration: Configures an RNS instance to complete basic configuration of the RNS test.
- Brief configuration: Configure and start an RNS instance at a time. (Optional)

#### Notes

- In the case of detailed configuration, if you do not further configure the test type after entering ip-ms mode, the RNS object cannot be created.
- In the case of detailed configuration, you must run the command to configure the startup policy after an IP RNS test is configured; otherwise, the test is not conducted.

#### Configuration Steps

##### ✚ Defining an IP RNS Operation Object

- Mandatory.
- Perform this configuration on every switching device unless otherwise required.
- Brief configuration is optional.

##### ✚ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

- Perform this configuration if it is required to configure the proactive threshold monitoring and triggering mechanism for the test.
- Perform this configuration on every switching device unless otherwise required.

##### ✚ Enabling an RNS Test to Trigger Another RNS Test

- Perform this configuration if it is required to trigger another type of the IP RNS test in pending state when the monitoring threshold exceeds the expectation during an IP RNS test.
- Perform this configuration on every switching device unless otherwise required.

##### ✚ Configuring the Schedule Parameters of an RNS Test

- Configure the scheduling method, start time, and life time if it is required to trigger an IP RNS test.
- Perform this configuration on every switching device unless otherwise required.
- In the case of brief configuration, this command is already configured using the default values, and manual configuration is not required.

### ↘ Restarting an IP RNS Test

- Perform this configuration, or directly run the **ip rns schedule X start-time now** command if it is required to restart an IP RNS instance in pending state.

### ↘ Clearing Configurations of All the IP RNS Instances

- Perform this configuration if it is required to clear configurations of all the IP RNS instances, for example, when a lot of instances are configured but configurations are found incorrect.

### ↘ Starting the IP RNS Server to Provide Server Functions

- Perform this configuration on every switching device unless otherwise required.

### Verification

- Run the **show ip rns configuration** command to display configurations of RNS instances.

### Related Commands

#### ↘ Defining an IP RNS Operation Object

<b>Command</b>	<b>ip rns operation-number</b>
<b>Parameter Description</b>	<i>operation-number</i> : Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>Currently, the IP RNS supports only IPv4-related tests, but not IPv6-related tests. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporarily disabled to ensure normal operation of core services, such as route forwarding.</p> <p>Detailed configuration (mandatory items of <b>ip rns operation-number</b>): Run this command and enter ip-rns mode. In ip-rns mode, you can define various test types. If the test type is not configured, the RNS object is not created. After configuring an IP RNS test, you must run the <b>ip rns schedule</b> command to configure its scheduling parameter; otherwise, the test cannot be conducted.</p> <p>After configuring an IP RNS test, you can run the <b>ip rns</b> command to directly enter the mode of the related test type. To modify a type of the IP RNS test object that is currently conducted, you must first delete this IP RNS test by running the <b>no ip rns</b> command in global configuration mode.</p>

#### ↘ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

<b>Command</b>	<b>ip rns reaction-configuration operation-number react monitored-element [action-type option] [threshold-type {average [number-of-measurements]   consecutive [occurrences]   immediate   never   xofy [x-value y-value]}] [threshold-value upper-threshold lower-threshold]</b>
<b>Parameter Description</b>	<p><i>operation-number</i>: Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500.</p> <p><i>monitored-element</i>: Specifies the monitored element.</p> <p><b>action-type option</b>: Indicates the action taken after the test is triggered.</p> <p><b>average [number-of-measurements]</b>: Indicates that the subsequent associated actions are triggered if the average of <i>number-of-measurements</i> of the monitored element exceeds the threshold.</p> <p><b>consecutive [occurrences]</b>: Indicates that the test is triggered if the consecutive number of <i>occurrences</i> of the</p>

	<p>monitored element exceeds the threshold. The default value of <i>occurrences</i> is 5. The value ranges from 1 to 16.</p> <p><b>immediate</b>: Indicates that the test is triggered immediately after the monitored element exceeds the threshold.</p> <p><b>never</b>: Indicates that the test is never triggered.</p> <p><b>xofy</b> [<i>x-value y-value</i>]: Indicates that results of X tests exceed the threshold in the last Y tests. The default values of X and Y are 5. The value of X or Y ranges from 1 to 16.</p> <p><b>threshold-value</b> <i>upper-threshold lower-threshold</i>: Indicate the upper and lower thresholds.</p> <ul style="list-style-type: none"> <li>When <i>monitored-element</i> is <b>rtt</b>, the thresholds are the time. For default values, see "Usage Guide". The value ranges from 0 to 60,000 ms.</li> <li>Note that you do not need to configure <b>threshold-value</b> when <b>react</b> is set to <b>timeout</b>.</li> </ul>		
<b>Command Mode</b>	Global configuration mode		
<b>Usage Guide</b>	For the same IP RNS object, you can configure multiple thresholds to monitor different elements. The following table provides the mapping between test types and monitored elements.		
	monitored-element	icmp-echo	dns
	timeout		
	rtt		
	The following table lists the default thresholds of each monitored element.		
	Monitored Element	Upper Threshold	Lower Threshold
	timeout	-	-
	rtt	5000ms	0ms

📌 **Enabling an RNS Test to Trigger Another RNS Test**

<b>Command</b>	<b>ip rns reaction-trigger</b> <i>operation-number target-operation</i>
<b>Parameter Description</b>	<p><i>operation-number</i>: Indicates the number of the source operation that triggers the action. The value ranges from 1 to 500.</p> <p><i>target-operation</i>: Indicates the number of the target operation that is triggered. The value ranges from 1 to 500.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	The trigger function is generally used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

📌 **Configuring the Schedule Parameters of an RNS Test**

<b>Command</b>	<b>ip rns schedule</b> <i>operation-number</i> [ <b>life</b> { <b>forever</b>   <i>seconds</i> } ] [ <b>start-time</b> { <i>hh:mm[:ss]</i> [ <i>month day</i>   <i>daymonth</i> ] } ] [ <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i> ] [ <b>recurring</b> ]
<b>Parameter Description</b>	<p><i>operation-number</i>: Indicates the number of the RNS operation. The value ranges from 1 to 500.</p> <p><b>lifeforever</b>: Indicates that the RNS operation life time is valid forever.</p> <p><b>lifeseconds</b>: Indicates the life time of the RNS in second.</p>

	<p><i>hh:mm[:ss]</i>: Accurately indicates the start time of the operation. The 24-hour format is used.</p> <p><i>month</i>: Indicates the start month of the operation. The default value is the current month.</p> <p><i>day</i>: Indicates the start date of the operation. The default value is the current date.</p> <p><b>pending</b>: Indicates that the operation start time is not defined yet. This is the default value.</p> <p><b>now</b>: Indicates that the operation start time is now, that is, the operation starts now.</p> <p><b>afterhh:mm:ss</b>: Indicates that the operation starts after a delay of hh:mm:ss.</p> <p><b>recurring</b>: Indicates whether the operation automatically starts every day at the same time.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>If the scheduling parameter of an IP RNS test is already configured by running the <b>ip rns schedule</b> command, its test parameters cannot be modified. To modify the configuration, you must run the <b>no ip rns schedule</b> command to delete the scheduling policy configuration.</p> <p><b>life{seconds}</b> indicates the lifecycle of the IP RNS test, that is, after the test is started according to the configured start time, the test stops after a period of time specified by <i>seconds</i>.</p>

↘ **Restarting an IP RNS Test**

<b>Command</b>	<b>ip rns restart</b> <i>operation-number</i>
<b>Parameter Description</b>	<i>operation-number</i> : Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command restarts an IP RNS test for which the scheduling policy is configured and is in pending state. This command is invalid for an IP RNS test for which the scheduling policy is not configured.

↘ **Clearing Configurations of All the IP RNS Instances**

<b>Command</b>	<b>ip rns reset</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command clears configurations of all the IP RNS instances. It is used only in extreme cases, for example, when a lot of RNS tests are configured but the configurations are found incorrect.

**Configuration Example**

↘ **Configuring RNS Basic Functions**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure instance 1 on Switch A.</li> <li>● Configure the scheduling method, start time, and life time of instance 1.</li> <li>● Configure the proactive threshold monitoring and triggering mechanism of instance 1.</li> <li>● Trigger instance 2 in pending state when the monitoring threshold of instance 1 exceeds the expectation.</li> </ul>
<b>Switch A</b>	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.1.1.1 A(config-ip-rns-icmp-echo)#exit A(config)ip rns schedule 1 start-time now life forever A(config)iprns reaction-configuration 1 reacttimeoutthreshold-type immediate action-type trigger A(config)ip rns reaction-trigger 1 2</pre>
<b>Verification</b>	<p>Run the <b>show ip rns configuration</b> command to display the instance configurations.</p> <pre>Router#show ip rns configuration 1 Entry number: 1 Tag: FS555 Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): 3500 Next Scheduled Start Time:Start Time already passed Target address/Source address: 2.2.2.3/0.0.0.0 Request size (ARR data portion): 36</pre>

## 9.4.2 Configuring the ICMP Echo Test

### Configuration Effect

Create an IP RNS test of the ICMP echo type.

### Notes

- The RNS basic functions must be configured.

### Configuration Steps

#### ↳ Creating an IP RNS Test of the ICMP Echo Type

- Mandatory.

- Perform this configuration on every switching device unless otherwise required.

#### ↘ Configuring Common Optional Parameters of the Test

- Perform this configuration if it is required to change common optional parameters of the test, such as the repeat interval, tag, time threshold, timeout, and TOS.
- Perform this configuration on every switching device unless otherwise required.

#### ↘ Configuring the Protocol Payload Size

- Perform this configuration if it is required to change the protocol payload size of the test.
- Perform this configuration on every switching device unless otherwise required.

#### Verification

- Run the **show ip rns configuration** command to display the instance configurations.

#### Related Commands

#### ↘ Creating an IP RNS Test of the ICMP Echo Type

<b>Command</b>	<b>icmp-echo</b> { <b>oob</b> { <i>destination-ip-address</i>   <i>destination-hostname</i> [ <b>name-server</b> <i>ip-address</i> ] } [ <b>source-ipaddr</b> <i>ip-address</i> ] <b>via</b> <i>type num</i> <b>next-hop</b> <i>ip-address</i> } } { { <i>destination-ip-address</i>   <i>destination-hostname</i> [ <b>name-server</b> <i>ip-address</i> ] } [ <b>source-ipaddr</b> <i>ip-address</i> ] [ <b>out-interface</b> <i>type num</i> [ <b>next-hop</b> <i>ip-address</i> ] ] }
<b>Parameter Description</b>	<p><b>oob</b>: Indicates the test on the MGMT interface.</p> <p><i>destination-ip-address</i>: Indicates the destination IP address.</p> <p><i>destination-hostname</i>: Indicates the destination host name.</p> <p><b>name-server</b> <i>ip-address</i>: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by using the <b>ipname-server</b> command is used for address resolution.</p> <p><b>source-ipaddr</b> <i>ip-address</i>: Indicates the source IP address.</p> <p><b>out-interface</b> <i>type num</i>: Specifies the outgoing interface (non-MGMT interface) of the test packet.</p> <p><b>via</b> <i>type num</i>: Specifies the MGMT interface as the outgoing interface of the test packet.</p> <p><b>next-hop</b> <i>ip-address</i>: Indicates the IP address of the next hop.</p>
<b>Command Mode</b>	IP RNS configuration mode (config-ip-rns)
<b>Usage Guide</b>	<p>After this command is configured, the IP RNS object starts to send the ICMP echo packet, and the destination IP address is the IP address configured by the user. By default, the payload size of an ICMP echo packet is 36 bytes. You can run the <b>request-data-size</b> command to change the packet size.</p> <p>You must first configure the type of the IP RNS test (such as the ICMP echo test), and then configure parameters of the test type. To modify the test type of an IP RNS test, you must first delete this IP RNS test by running the <b>no ip rns</b> command in global configuration mode.</p>

#### ↘ Configuring the Protocol Payload Size of the IP RNS Test

<b>Command</b>	<b>request-data-size</b> <i>bytes</i>
<b>Parameter Description</b>	<i>bytes</i> : Indicates the bytes of the test packet. The minimum/maximum bytes vary according to the test type. You need to configure this item based on the command prompt in configuration mode of a specific test.

<b>Command Mode</b>	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	This command is used to stuff some bytes in the test packet so that large packets can be used for the test.

#### ▾ Configuring the Test Repeat Interval

<b>Command</b>	<b>frequency</b> <i>milliseconds</i>
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	Tests are conducted periodically in an IP RNS test lifecycle. You can run the <b>frequency</b> command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test: <b>(frequency milliseconds) &gt; (timeout milliseconds) &gt;= (threshold milliseconds)</b>

#### ▾ Configuring a Tag for an IP RNS Test

<b>Command</b>	<b>tag</b> <i>text</i>
<b>Parameter Description</b>	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	This command specifies a tag for a test, which is often used to indicate the function of the test.

#### ▾ Configuring the Time Threshold of an IP RNS Test

<b>Command</b>	<b>threshold</b> <i>milliseconds</i>
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the time threshold of the test. The value ranges from 0 to 60,000. The unit is ms. The default value is 5,000.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	The value of <b>threshold</b> must be equal to or smaller than the value of <b>timeout</b> . For the relationship between <b>timeout</b> , <b>frequency</b> , and <b>threshold</b> , see "Usage Guide" of the <b>frequency</b> command.

#### ▾ Configuring the Timeout of an IP RNS Test

<b>Command</b>	<b>timeout</b> <i>millisecond</i>
<b>Parameter Description</b>	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.

<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	The value of <b>timeout</b> must be equal to or greater than the value of <b>threshold</b> . For the relationship between <b>timeout</b> , <b>frequency</b> , and <b>threshold</b> , see "Usage Guide" of the <b>frequency</b> command.

### Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

<b>Command</b>	<b>tos number</b>
<b>Parameter Description</b>	<i>number</i> : Sets the TOS field in the IPv4 test packet. The value ranges from 0 to 255. The default value is 0.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

### Configuring the VRF of an IP RNS Test

<b>Command</b>	<b>vrf vrf-name</b>
<b>Parameter Description</b>	<i>vrf-name</i> : Specifies the VRF name.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	This command specifies the VRF of the test packet.

### Configuration Example

<b>Figure 9-3</b>	 <p>Switch A</p> <p>Switch B</p>
	Configure RNS instance 1 and related parameters on Switch A.
<b>Switch A</b>	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.2.2.2 A(config-ip-rns-icmp-echo)#exit A(config)#ip rns schedule 1 start-time now life forever</pre>
	Run the <b>show ip rns configuration</b> command to display the instance configurations.

<b>Switch A</b>	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): forever Next Scheduled Start Time: Start Time already passed TaFSetaddress/Sourceaddress: 10.2.2.2/0.0.0.0 Request size (ARR data portion): 36</pre>
-----------------	---

### 9.4.3 Configuring the DNS Test

#### Configuration Effect

Create an IP RNS test of the DNS type and implement the DNS test.

#### Notes

- The RNS basic functions must be configured.

#### Configuration Steps

##### ↘ Creating an IP RNS Test of the DNS Type

- Mandatory.
- Perform this configuration on every switching device unless otherwise required.

##### ↘ Configuring Common Optional Parameters of the Test

- Perform this configuration if it is required to change common optional parameters of the test, such as the repeat interval, tag, time threshold, timeout, and TOS.
- Perform this configuration on every switching device unless otherwise required.

#### Verification

- Run the **show ip rns configuration** command to display the instance configurations.

#### Related Commands

##### ↘ Creating an IP RNS Test of the DNS Type

<b>Command</b>	<b>dns { oob destination-hostname name-server ip-address }</b>
<b>Parameter Description</b>	<b>oob</b> : Indicates the test on the MGMT interface. <b>destination-hostname</b> : Indicates the destination host name. <b>name-server ip-address</b> : Indicates the IP address of the DNS server.
<b>Command</b>	IP RNS configuration mode (config-ip-rns)

<b>Mode</b>	
<b>Usage Guide</b>	You must first configure the type of the IP RNS test (such as the ICMP echo test), and then configure parameters of the test type. To modify the test type of an IP RNS test, you must first delete this IP RNS test by running the <b>no ip rns</b> command in global configuration mode.

#### ↘ Configuring the Test Repeat Interval

<b>Command</b>	<b>frequency</b> <i>milliseconds</i>
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	Tests are conducted periodically in an IP RNS test lifecycle. You can run the <b>frequency</b> command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test: <b>(frequency milliseconds) &gt; (timeout milliseconds) &gt;= (threshold milliseconds)</b>

#### ↘ Configuring a Tag for an IP RNS Test

<b>Command</b>	<b>tag</b> <i>text</i>
<b>Parameter Description</b>	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	This command specifies a tag for a test, which is often used to indicate the function of the test.

#### ↘ Configuring the Upper Threshold of an RNS Test

<b>Command</b>	<b>threshold</b> <i>milliseconds</i>
<b>Parameter Description</b>	<i>milliseconds</i> : Indicates the upper threshold of the test. The value ranges from 0 to 60,000. The unit is ms. The default value is 5,000.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	The value of <b>threshold</b> must be equal to or smaller than the value of <b>timeout</b> . For the relationship between <b>timeout</b> , <b>frequency</b> , and <b>threshold</b> , see "Usage Guide" of the <b>frequency</b> command. The value of <b>threshold</b> must be smaller than the value of <b>timeout</b> .

#### ↘ Configuring the Timeout of an IP RNS Test

<b>Command</b>	<b>timeout</b> <i>millisecond</i>
<b>Parameter</b>	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout

<b>Description</b>	varies according to the test type.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	The value of <b>timeout</b> must be equal to or greater than the value of <b>threshold</b> . For the relationship between <b>timeout</b> , <b>frequency</b> , and <b>threshold</b> , see "Usage Guide" of the <b>frequency</b> command.

#### ✎ Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

<b>Command</b>	<code>tos number</code>
<b>Parameter Description</b>	<i>number</i> : Sets the TOS field in the IPv4 test packet. The value ranges from 0 to 255. The default value is 0.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

#### ✎ Configuring the VRF of an IP RNS Test

<b>Command</b>	<code>vrf vrf-name</code>
<b>Parameter Description</b>	<i>vrf-name</i> : Specifies the VRF name.
<b>Command Mode</b>	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
<b>Usage Guide</b>	This command specifies the VRF of the test packet.

#### Configuration Example

<b>Scenario</b> Figure 9-4	
<b>Configuration Steps</b>	Configure RNS instance 1 and related parameters on Switch A.
<b>Switch A</b>	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)# dns www.FS.com.cn name-server 10.2.2.2 A(config-ip-rns-dns)#exit A(config)# ip rns schedule 1 start-time now life forever</pre>
<b>Verification</b>	Run the <b>show ip rns configuration</b> command to display the instance configurations.

<b>Switch A</b>	<pre>A#showiprns configuration 1 Entry number: 1 Tag: Type of operation to perform: dns Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): forever Next Scheduled Start Time: Start Time already passed TaFSet host name: www.FS.com.cn Name Server: 10.2.2.2</pre>
-----------------	---

#### Common Errors

- The IP address of the server is incorrect.

#### 9.4.4 Configuring the Track Support for the RNS

##### Configuration Effect

- Configure the track function to track the test result of an RNS instance.
- Configure the track function to track the link status of an interface.
- Configure the track function to track the status of a track list.
- Configure the track function to track the status of an RNS list.

##### Notes

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.

##### Configuration Steps

##### 📄 Configuring a Track Object

- Perform this operation if it is required to create a track object.
- The following four methods are available to create a track object:

-Create a track object for tracking the test result of an RNS instance: Perform this configuration on every switching device unless otherwise required.

- Create a track object for tracking the link status of an interface: Perform this configuration on every switching device unless otherwise required.
- Create a track object for tracking the status of a track list: Perform this configuration on every switching device unless otherwise required.
- Create a track object for tracking the status of an RNS list: Perform this configuration on every switching device unless otherwise required.

#### ✚ Configuring the Notification Delay of a Track Object

- Perform this configuration if it is required to delay notification of the status change of a track object.
- Delay for notifying the status change of a track object includes the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. You can configure either delay or both of delays.
- Perform this configuration on every switching device unless otherwise required.

#### ✚ Configuring a Track Member

- Perform this configuration if it is required to configure a track object for tracking the status of a track list.
- When configuring a track member, you can set the status of a member meeting conditions to UP or DOWN.
- Perform this configuration on every switching device unless otherwise required.

#### Verification

Observe the status of a track object when the status of the track object (such as test results of an RNS instance, link status of an interface, or status of a track list) changes.

- After the preset delay, run the **show track** command to check whether the current track status changes.

#### Related Commands

##### ✚ Configuring a Track Object for Tracking the Link Status of An Interface

<b>Command</b>	<b>track object-number interface interface-type interface-number line-protocol</b>
<b>Parameter</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
<b>Description</b>	<i>Interface-type interface-number</i> : Indicates the interface type and interface number.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is UP, the status of the corresponding track object is UP.

##### ✚ Configuring a Track Object for Tracking the Test Result of an RNS Instance

<b>Command</b>	<b>track object-number rns entry-number</b>
<b>Parameter</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
<b>Description</b>	<i>entry-number</i> : Indicates the number of an RNS object. The value ranges from 1 to 500.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure a track object for tracking the test result of an RNS instance. When the test result of the RNS instance is successful, the status of the corresponding track object is UP.

### ✚ Configuring a Track Object for Tracking the Status of a Track List

<b>Command</b>	<b>track object-number listboolean { and   or }</b>
<b>Parameter Description</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of all member status.

### ✚ Configuring a Track Member

<b>Command</b>	<b>object object-number[ not ]</b>
<b>Parameter Description</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
<b>Command Mode</b>	Track configuration mode
<b>Usage Guide</b>	Run this command to configure a member for a track list. The number of track list members that can be configured is restricted only by the capacity of track objects.

### ✚ Configuring a Track Object for Tracking the Status of an RNS List

<b>Command</b>	<b>track object-number rns-list mem-list{ and   or }</b>
<b>Parameter Description</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. <i>mem-list</i> : Indicates the RNS list that is tracked. <b>mem-list</b> can be an RNS instance or a series of RNS instances. If <b>mem-list</b> is a series of RNS instances, the format is as follows: Smallest RNS ID–Greatest RNS ID, for example, 10–20. The RNS ID ranges from 1 to 500.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to configure a track object for tracking the status of an RNS list. The result can be the AND or OR operation result of all member status.

### Configuring the Notification Delay of a Track Object

<b>Command</b>	<b>delay { upseconds [ downseconds ]   [ upseconds ] downseconds }</b>
<b>Parameter Description</b>	<b>up seconds</b> : Specifies the delay for notifying the status change of a track object from DOWN to UP. The value ranges from 0 to 180. The unit is second. The default value is 0. <b>downseconds</b> : Specifies the delay for notifying the status change of a track object from UP to DOWN. The value ranges from 0 to 180. The unit is second. The default value is 0.
<b>Command Mode</b>	Track configuration mode
<b>Usage Guide</b>	When the status of a track object frequently changes, the status of the client that use this track object will frequently change as well. Using this command can delay notification of the status change of a track object. For example, if the status of a track object changes from UP to DOWN, and <b>delay down 10</b> is configured, the DOWN status of the track object is notified 10s later. If the status of the track objects changes to UP again within this period of time, no notification is sent. For the client that uses this track object, the status of the track object is always UP.

### ▾ Displaying the Track Object Statistics

<b>Command</b>	<b>showtrack</b> [ <i>object-number</i> ]
<b>Parameter Description</b>	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. The default is all track objects.
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Run this command to display statistics of track objects.

### Configuration Example

#### ▾ Configuring Track Object3 for Tracking the Link Status of the Interface FastEthernet 1/0

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure a track object for tracking the link status of an interface.</li> <li>● Configure the delay for notifying the status change from UP to DOWN.</li> </ul>
	<pre> FS# configure terminal FS(config)# track 3 interface FastEthernet 1/0 line-protocol FS(config-track)# delay down 10 FS(config-track)# exit </pre>
<b>Verification</b>	<p>Change the link status of the interface FastEthernet 1/0 to DOWN.</p> <ul style="list-style-type: none"> <li>● Immediately check the status of the track object, and verify that the status is still UP.</li> <li>● Check the status of the track object 10s later, and verify that the status changes to DOWN.</li> </ul>
	<pre> FS# show track 3 Track 3   Interface FastEthernet 1/0   The state is Up, delayed Down (5 secs remaining)   1 change, current state last: 300 secs   Delay up 0 secs, down 10 secs </pre>

#### ▾ Configuring Track Object3 (When the status of track object 1 is UP, and the status of track object 2 is DOWN, the status of track object 3 is UP.)

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configuring track object 1 and track object 2.</li> <li>● Configure track object 3, and its members include track object 1 and track object 2.</li> </ul>
----------------------------	--

	<pre> FS # config FS(config)#track 1 interface gigabitEthernet 0/0 line-protocol FS(config-track)#delay up 20 down 40 FS(config-track)#exit FS(config)# FS(config)#track 2 interface gigabitEthernet 0/1 line-protocol FS(config-track)#delay down 30 FS(config-track)#exit FS(config)#track 3 list Boolean and FS(config-track)#object 1 FS(config-track)#object 2 not FS(config-track)# exit                     </pre>
<b>Verification</b>	<p>When the status of track objects 1 and 2 change, check the status of track object 3.</p> <ul style="list-style-type: none"> <li>● When the status of track object 1 changes from DOWN to UP, and the status of track object 2 remains DOWN, verify that the status of track object 3 changes from DOWN to UP.</li> <li>● When the status of track object 1 remains UP, and the status of track object 2 changes from DOWN to UP, verify that the status of track object 3 changes from UP to DOWN.</li> </ul>
	<pre> FS# show track 3  Track 3   List boolean and   Object 1   Object 2 not   The state is Down     1 change, current state last: 10 secs   Delay up 0 secs, down 0 secs                     </pre>

📌 **Configuring Track Object 5 for Tracking the Test Result of RNS Instance 7**

<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an RNS instance.</li> <li>● Configure a track object for tracking the test result of an RNS instance.</li> <li>● Configure the delay for notifying the test result change from successful to unsuccessful, and the delay for notifying the test result change from unsuccessful to successful.</li> </ul>
	<pre> FS# configure terminal FS (config)#ip rns 7 FS (config-ip-rns)#icmp-echo 2.2.2.2                     </pre>

	<pre>FS (config-ip-rns-icmp-echo)#exit FS (config)#ip rns schedule 7 start-time now life forever FS(config)# track 5 rns 7 FS (config-track)# delay up 20 down 30 FS (config-track)# exit</pre>
<b>Verification</b>	<p>Let the test result of RNS instance 7 change from successful to unsuccessful.</p> <ul style="list-style-type: none"> <li>● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP.</li> <li>● Check the status of the track object 30s later, and verify that the status changes to DOWN.</li> </ul>
	<pre>FS# show track 5 Track 5 Reliable Network Service 7 The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs</pre>

📌 **Configuring Track Object 5 for Tracking the Test Results of an RNS List (consisting of RNS Instances 1, 2–5, and 8)**

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure and start the RNS.</li> <li>● Configure a track object for tracking the test result of an RNS list.</li> <li>● Configure the delay for notifying the test result change from UP to DOWN, and the delay for notifying the test result change from DOWN to UP.</li> </ul>
	<pre>FS(config)# track 5 rns-list 1,2-5,8 and FS (config-track)# delay up 20 down 30 FS (config-track)# exit</pre>
<b>Verification</b>	<p>Let the test result of one of the RNS instances 1, 2-5, and 8 changes from successful to unsuccessful.</p> <ul style="list-style-type: none"> <li>● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP.</li> <li>● Check the status of the track object 30s later, and verify that the status changes to DOWN.</li> </ul>
	<pre>FS# show track 5 Track 5 rns-list 1,2-5,8 and The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs</pre>

**Common Errors**

- The track object for tracking an RNS instance is configured, but the corresponding RNS instance is not configured.
- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.
- The track object for tracking the status of a track list, but no member of the RNS list is configured.
- The track object for tracking the status of an RNS list is configured, but the corresponding RNS instance is not configured.

## 9.5 Monitoring

### Displaying

Description	Command
Displays configurations of one or more RNS instances.	<b>show ip rns configuration</b> [ <i>operation-number</i> ]
Displays detailed statistics of one or more RNS instances.	<b>show ip rns collection-statistics</b> [ <i>operation-number</i> ]
Displays the current RNS status.	<b>show ip rns operational-state</b> [ <i>operation-number</i> ]
Displays the proactive threshold monitoring information of one or more RNS instances.	<b>show ip rns reaction-configuration</b> [ <i>operation-number</i> ]
Displays information about the test triggered by one or more RNS instances.	<b>show ip rns reaction-trigger</b> [ <i>operation-number</i> ]
Displays the brief statistics of one or more RNS instances.	<b>show ip rns statistics</b> [ <i>operation-number</i> ]
Displays the brief statistics of one or more track objects.	<b>show track</b> [ <i>object-number</i> ]
Displays the brief statistics of a track client.	<b>show track client</b>

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the track module.	<b>debug track</b> { <b>all</b>   <b>proc-event</b>   <b>rdnd-event</b>   <b>client</b> }
Debugs the RNS module.	<b>debug rns</b> { <b>all</b>   <b>interface</b>   <b>lib</b>   <b>rdnd-event</b>   <b>restart</b>   <b>rns_id</b> [ <b>0</b> , <b>500</b> ] }

## 10 Configuring PCAP

### 10.1 Overview

Packet Capture (PCAP) is a maintenance function commonly used in network devices.

Similar to the packet capture software running on a personal computer, the PCAP function can capture, save, or display the packets sent from and received by the network device.

## 10.2 Applications

Application	Description
<a href="#">Capturing Packets</a>	During routine maintenance, if you find packet sending or receiving failures in the network, specify the capture point and capture direction, enter the packet feature, and start the packet capture to check whether the packets arrives at the device or are sent from the device.

### 10.2.1 Capturing Packets

#### Scenario

During routine maintenance, if you find packet sending or receiving failures in the network, specify the capture point and capture direction, enter the packet feature, and start the packet capture to check whether the packets arrives at the device or are sent from the device.

#### Deployment

Perform packet capture as follows:

- Create a capture feature rule and name it.
- Create a capture point and specify the capture point name, capture location (physical port, VLAN, and control plane), capture direction, and capture feature.
- Specify the name of the file to be saved.
- Enable packet capture at the capture point.
- Wait until the capture ends.
- Upload the file to the PC.
- Enable the capture software on the PC to check the captured packets.

## 10.3 Features

#### Overview

Feature	Description
<a href="#">Capturing Packets on Control Plane</a>	Clients can define the capture point and specify the capture location and direction, matching rule information, number of captured packets, and file name; and then enable the capture procedure.
<a href="#">Capturing Packets on Forwarding Plane</a>	Users can specify rules of matching between ACL IDs and physical ports (ACL IDs are mandatory and physical ports are optional), number of to-be-captured packets, name of the file for storing captured packets, and other information, and then start the packet capture.

### 10.3.1 Capturing Packets on Control Plane

Clients can define the capture point and specify the capture location and direction, matching rule information, number of captured packets, and file name; and then enable the capture procedure.

#### Working Principle

Clients can define the capture rules by defining capture points. To capture multiple types of packets at the same time, a client is allowed to define multiple capture points and distinguish them by their names.

The capture rules are as follows:

- 1) The capture location can be selected from the certain physical port, VLAN port, and system control plane. Each capture point can only have one capture location.
- 2) The available capture directions can be the outgoing direction, incoming direction, and bidirectional.
- 3) The 7-tuple information can match the source MAC address, destination MAC address, layer-2 protocol type, source IP address, destination IP address, layer-3 protocol type, and TCP/UDP port information.
- 4) The number of captured packets or size of the captured packet can be specified.
- 5) The file name can be specified. The captured packet will be saved in PCAP file format.

A client enables capture via commands after the rules are configured. The capture will automatically stop when the number of captured packets or the file size reaches the specified value, or when timeout happens. The client can also stop the capture after commands are entered manually.

### 10.3.2 Capturing Packets on Forwarding Plane

Users can specify rules of matching between ACL IDs and physical ports (ACL IDs are mandatory and physical ports are optional), number of to-be-captured packets, name of the file for storing captured packets, and other information, and then start the packet capture.

#### Working Principle

1. The rule of matching between ACL IDs and physical ports can be specified for packet capture and physical ports are optional.
2. Multiple rules of matching between ACL IDs and physical ports can be configured for packet capture.
3. Packet capture at the ingress is supported.
4. No packet capture point needs to be specified and 7-tuple matching information is not supported.
5. The number of to-be-captured packets or the size of the file for storing captured packets can be defined.
6. Captured packets are stored in a specified file in the PCAP file format. Users can run commands to start packet capture after configuring rules. The capture automatically stops when the number of captured packets or the file size reaches the specified value or when timeout occurs. Users can also run commands to manually stop packet capture.

## 10.4 Configuration

Configuration	Description and Command
<a href="#">Capturing Packets on Control Plane</a>	<pre>packet capture rule rule-name filter [src-mac smac] [dst-mac dmac][etype type   ip arp] [ipv4-sip sip sip-mask] [ipv4-dip dip dip- mask] [ipv6-sip sipv6 sipv6-prefix] [ipv6_dip dipv6 dipv6-prefix] [v6_protocol protocol   tcp  udp] [ipv6_sport</pre> <p>Defines capture matching rule.</p>

	<i>sport</i> ] [ <i>ipv6_dport dport</i> ] [ <i>v4_protocol protocol</i>   <i>tcp   udp</i> ] [ <i>ipv4_sport sport</i> ] [ <i>ipv4_dport dport</i> ]	
	<b>packet capture point</b> <i>capture-point-name rule rule-name location</i> { <i>interface interface-name</i>     <i>control-plane</i> } { <i>in   out   both</i> }	Creates the capture point and specifies the capture location, matching rule, and capture direction.
	<b>packet capture file</b> <i>filename</i> [ <i>buffer-size buf-size</i> ] [ <i>packet-num pkt-num</i> ] [ <i>timeout timeout</i> ]	Specifies the name of the file to be saved.
	<b>packet capture</b> { <i>start   stop</i> }	Starts/Stops packet capture.
<u>Capturing Packets on Forwarding Plane</u>	<b>packet capture rule</b> <i>rule-name filter acl aclid   aclname</i> [ <i>interface interface-name</i> ]	Defines capture matching rule.
	<b>packet capture file</b> <i>filename</i> [ <i>buffer-size buf-size</i> ][ <i>packet-num pkt-num</i> ] [ <i>timeout timeout</i> ]	Specifies the name of the file to be saved.
	<b>packet capture</b> { <i>start   stop</i> }	Starts/Stops packet capture.

#### 10.4.1 Capturing Packets on Control Plane

##### Configuration Effect

- Define the capture matching rule.
- Create the capture point.
- Specify the name of the file to be saved.
- Start packet capture.
- Stop packet capture.

##### Configuration Steps

##### ▾ Defining Capture Matching Rule

- (Mandatory) Run this command to define the packet capture rule.

<b>Command</b>	<b>packet capture rule</b> <i>rule-name filter</i> [ <i>src-mac smac</i> ] [ <i>dst-mac dmac</i> ] [ <i>etype type   ip   arp</i> ] [ <i>ipv4_sip sip sip-mask</i> ] [ <i>ipv4_sip dip dip-mask</i> ] [ <i>ipv6_sip sipv6 sipv6-prefix</i> ] [ <i>ipv6_dip dipv6 dipv6-prefix</i> ] [ <i>v6_protocol protocol   tcp   udp</i> ] [ <i>ipv6_sport sport</i> ] [ <i>dst-port dport</i> ] [ <i>v4_protocol protocol   tcp   udp</i> ] [ <i>ipv4_sport sport</i> ] [ <i>dst-port dport</i> ]
<b>Parameter Description</b>	<i>rule-name</i> : Indicates the matching rule name. <i>smac</i> : Indicates the source MAC address. <i>dmac</i> : Indicates the destination MAC address. <i>type   ip   arp</i> : Indicates the layer-2 protocol type. <i>sip</i> : Indicates the source IP address. <i>sip-mask</i> : Indicates the source IP address mask. <i>dip</i> : Indicates the destination IP address. <i>dip-mask</i> : Indicates the destination IP address mask. <i>sipv6</i> : Indicates the source IPv6 address. <i>sipv6-prefix</i> : Indicates the source IPv6 prefix. <i>dipv6</i> : Indicates the destination IPv6 address. <i>sipv6-prefix</i> : Indicates the destination IPv6 prefix.

	<p><i>protocol</i>   <b>tcp</b>   <b>udp</b>: Indicates the layer-3 protocol type.</p> <p><i>sport</i>: Indicates the TCP/UDP protocol source port.</p> <p><i>dport</i>: Indicates the TCP/UDP protocol destination port.</p>
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The user can define multiple capture rules and distinguish them by different names. After a rule is defined, the rule needs to be referenced by the packet capture point to actually take effect.</li> <li>2. Before deleting the capture rule, all the packet capture points referencing the rule need to be deleted.</li> </ol>

### ↘ Creating Capture Point

- (Mandatory) Run this command to create the capture point.

<b>Command</b>	<b>packet capture point</b> <i>capture-point-name</i> <b>rule</b> <i>rule-name</i> <b>location</b> { <b>interface</b> <i>interface-name</i>   <b>control-plane</b> } { <b>in</b>   <b>out</b>   <b>both</b> }
<b>Parameter Description</b>	<p><i>capture-point-name</i>: Indicates the capture point name.</p> <p><i>rule-name</i>: Indicates the matching rule name, which is defined by running the <b>packet capture rule</b> command.</p> <p><i>interface-name</i>: Indicates the name of the port on which packets are captured.</p> <p><i>vlan-id</i>: Indicates the ID of the VLAN in which packets are captured.</p> <p><b>control-plane</b>: Indicates the control plane on which packets are captured.</p> <p><b>in</b>   <b>out</b>   <b>both</b>: Indicates the capture direction (incoming, outgoing, or bidirectional).</p>
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The user can define multiple capture points at the same location as required to match different capture rules or packet directions. The capture points can work simultaneously without affecting each other.</li> <li>2. If the capture point is modified during packet capture, the modification will not take effect immediately and will take effect next time when packet capture is enabled.</li> </ol>

### ↘ Specifying Name of File to Be Saved

- (Optional) Run this command to specify the name of the file to be saved.

<b>Command</b>	<b>packet capture file</b> <i>filename</i> [ <b>buffer-size</b> <i>buf-size</i> ] [ <b>packet-num</b> <i>pkt-num</i> ] [ <b>timeout</b> <i>timeout</i> ]
<b>Parameter Description</b>	<p><i>filename</i>: Indicates the name of the file to be saved.</p> <p><i>buf-size</i>: Indicates the buffer size. The buffer size is 2 MB by default if not specified. Packet capture automatically stops when the buffer is full. Up to 200M buffer is supported.</p> <p><i>pkt-num</i>: Indicates the number of captured packets. Packet capture automatically stops when the number of captured packets reaches the specified number. 1024 packets will be captured continually by default unless otherwise specified.</p> <p><i>timeout</i>: Indicates packet capture timeout. Packet capture automatically stops when the time of captured packets reaches the specified number. The default packet capture time is 10 minutes unless otherwise specified. The longest continually packet capture time is 120 minutes.</p>
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. The file name setting takes effect next time packet capture is enabled.</li> </ol>

📄 **Starting/Stopping Packet Capture**

- (Mandatory) Enter this command to start or stop packet capture.

<b>Command</b>	<b>packet capture { start   stop}</b>
<b>Parameter</b>	<b>start   stop:</b> Starts/Stops packet capture.
<b>Description</b>	
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. If the packet capture stop command is not entered after packet capture starts, the packet capture automatically stops at the capture point when the number of captured packets reaches the specified number. If the packet capture stop condition is not met, run this command to immediately stop the packet capture.</li> <li>2. Run the packet capture start command to capture packets at all packet capture points simultaneously.</li> </ol>

**Verification**

Run the **show packet capture status** command to display packet capture information.

<b>Command</b>	<b>show packet capture status</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Run this command to display the packet capture status.
<b>Command Presentation</b>	<pre> FS#show packet capture status  Capture rules:    Capture rules tcp:     etype: 0x0800     source MAC: 2222.2222.2222     destination MAC: 1111.1111.1111     protocol: 0x6     source IP: 10.10.10.3     destination IP: 10.10.10.10     source port: 5     destination port: 10  Capture points:    Capture point controlplane:     Capture rules: tcp                     </pre>

	<pre>location: control-plane direction: all  Capture file:   Filename: /tmp/tcp.pcap   Buffer size: 2(MB)   Capture Statistic: Status: stop Stop reason: Normal Start time: 2017-5-20 9:24:19 End time: 2017-5-20 9:28:19 Timeout: 10(minutes) Packets limit: 1024 Packet capture cnts:10  FS#</pre>
--	--

## Configuration Example

### 📄 Capturing Packets

<b>Scenario</b>	<ul style="list-style-type: none"> <li>In the client environment, the TCP connection of a certain application on a device connected to Port 0/1 fails, TCP packets need to be captured on this port for analysis.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Run the packet capture command to capture and save TCP packets to the file tcp.pcap and upload the file to a PC to display the captured data.</li> </ul>
	<pre>FS# packet capture rule tcp etype ip protocol tcp FS# packet capture point tcppoint rule tcp location interface gi0/1 both FS# packet capture file usb0:tcp.pcap packet-num 1500 FS# packet capture start</pre>
<b>Verification</b>	<pre>FS#show packet capture status</pre> <p>Capture rules:</p> <p>Capture rules tcp:</p> <pre>  etype: 0x0800   protocol: 0x6</pre> <p>Capture points:</p> <p>Capture point tcppoint:</p> <pre>  Capture rules: tcp   location: Gi0/1   direction: all</pre> <p>Capture file:</p> <pre>  Filename: /mnt/usb0/tcp.pcap   Buffer size: 2(MB)</pre> <p>Capture Statistic:</p> <pre>  Status: running   Timeout: 10(minutes)   Packets limit: 1500   Packet capture cnts:10</pre>

### 10.4.2 Capturing Packets on Forwarding Plane

#### Configuration Effect

- Define the capture matching rule.
- Specify the name of the file to be saved.

- Start packetcapture.
- Stop packetcapture.

## Configuration Steps

### ▾ Defining Capture Matching Rule

- (Mandatory) Run this command to define the packet capture rule.

<b>Command</b>	<b>packet capture rule</b> <i>rule-name</i> <b>filter acl</b> <i>aclid</i> [ <b>interface</b> <i>interface-name</i> ]
<b>Parameter</b>	<i>rule-name</i> : Indicates the matching rule name.
<b>Description</b>	<i>aclid</i> : Indicates the ACL ID or name. <i>interface-name</i> : Indicates the interface.
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	The user can define multiple capture rules and distinguish them by different names. After a rule is defined, the rule needs to be referenced by the packet capture point to actually take effect.

### ▾ Specifying Name of File to Be Saved

- (Optional) Run this command to specify the name of the file to be saved.

<b>Command</b>	<b>packet capture file</b> <i>filename</i> [ <b>buffer-size</b> <i>buf-size</i> ] [ <b>packet-num</b> <i>pkt-num</i> ] [ <b>timeout</b> <i>timeout</i> ]
<b>Parameter</b>	<i>filename</i> : Indicates the name of the file to be saved.
<b>Description</b>	<i>buf-size</i> : Indicates the buffer size. The buffer size is 2 MB by default if not specified. Packet capture automatically stops when the buffer is full. Up to 200 MB buffer is supported. <i>pkt-num</i> : Indicates the number of captured packets. Packet capture automatically stops when the number of captured packets reaches the specified number. 1024 packets will be captured continually by default unless otherwise specified. <i>timeout</i> : Indicates packet capture timeout. Packet capture automatically stops when the time of captured packets reaches the specified number. The default packet capture time is 10 minutes unless otherwise specified. The longest continually packet capture time is 120 minutes.
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	1. The file name setting takes effect next time packet capture is enabled.

### ▾ Starting/Stopping Packet Capture

- (Mandatory) Enter this command to start or stop packet capture.

<b>Command</b>	<b>packet capture { start   stop }</b>
<b>Parameter</b>	<b>start   stop</b> : Starts/Stops packet capture.
<b>Description</b>	
<b>Defaults</b>	-
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	If the packet capture stop command is not entered after packet capture starts, the packet capture automatically

	stops at the capture point when the number of captured packets reaches the specified number. If the packet capture stop condition is not met, run this command to immediately stop the packet capture.
--	--

**Verification**

Run the **show packet capture status** command to display packet capture information.

<b>Command</b>	<b>show packet capture status</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	Run this command to display the packet capture status.
<b>Command Presentation</b>	<pre>FS#show packet capture status  Capture rules:    Capture rules rule1:      acl_id: 1  Capture file:    Filename: /tmp/vsd/0/test.pcap    Buffer size: 2(MB)  Capture Statistic:    Status: stopped    Stopped reason: Normal    Timeout: 10(minutes)    Packets limit: 1024    Write file packet count: 0  FS#</pre>

**Configuration Example**

📄 **Capturing Packets**

<b>Scenario</b>	<ul style="list-style-type: none"> <li>In the client environment, a traffic error occurs to interface 0/1. Traffic may not reach the device. Therefore, packets need to be captured on this port for analysis.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Run the packet capture command to capture and save TCP packets to the file tcp.pcap and upload the file to a PC to display the captured data.</li> </ul>
	<pre>FS(config)#access-list 100 permit tcp host 1.1.1.1 any FS(config)#exit FS#packet capture rule rule1 filter acl 100 interface tenGigabitEthernet 0/1</pre>

	<pre>FS# packet capture file usb0:tcp.pcap packet-num 1500 FS# packet capture start</pre>
<b>Verification</b>	<pre>FS#show packet capture status  Capture rules:   Capture rules rule1:     acl_id: 100     acl_ifx: TenGigabitEthernet 0/1  Capture file:   Filename: /tmp/vsd/0/test.pcap   Buffer size: 2(MB)  Capture Statistic:   Status: running   Start time: 2018-6-4 16:34:55   Timeout: 10(minutes)   Packets limit: 1024   Write file packet count: 4</pre>

## 10.5 Monitoring

### Displaying

Description	Command
Displays the packet capture status.	<b>show packet capture status</b>

## 10.6 Restrictions on the Packet Capture Function

- Packet capture cannot be configured on the MGMT port but on physical ports.
- Packet capture cannot be configured on SVIs or VSL interfaces.
- The packet capture configuration cannot be saved.
  - The packet capture configuration is lost after the `efmp_frame.elf` process or device is restarted.
  - VSU configuration cannot be synchronized. If packet capture is configured on the active VSU, the packet capture configuration will be lost after active/standby switchover.
- Interfaces of non-master member devices cannot be configured as packet capture interfaces. Aggregation port (APs) whose member ports include interfaces of non-master member devices can be configured as packet capture interfaces.

5. Either control plane packet capture rules or forwarding plane packet capture rules can be configured at a time. The two types of rules are mutually exclusive.
6. Packet capture is available only when the permit entry is configured in forwarding plane ACL rules. The deny entry in rules does not support packet capture by default.
7. The forwarding plane PCAP function takes effect only on incoming packets. It does not send outgoing packets to the CPU.
8. Packet capture on APs (depending on project requirements):
  - (1) On devices used in early projects such as **N18000\_FSOS 11.3(1)B1 R(M08282403212015)**, the forwarding plane packet capture function is available only on physical ports but unavailable on APs.
  - (2) On certain devices used in some released projects such as **N8560\_FSOS 11.0(5)B9P43 R(M10544905142019)**, packet capture can be enabled on APs by running commands (some products do not support packet capture on member ports of APs due to chip limitations).
  - (3) On devices used in new projects such as **FSOS 11.0(5)B9P36 R(M20524506292019)**, packet capture is supported on APs (including member ports).

## 11 Configuring HAM

### 11.1 Overview

1. The High Availability Module (HAM) is a high availability technology of the system.
2. HAM can start a process when it exits.
3. HAM detects whether a process exits after the device is started. If a process that registers with the HA service exits frequently, HAM starts the HA service and automatically restarts the device. To address possible abnormalities in the patch-based upgrade, CLI commands are added to enable/disable the HA service of a process that restarts frequently.

#### Protocols and Standards

- HAM is a proprietary protocol.

### 11.2 Applications

Application	Description
<a href="#">HA Service for Starting a Process When the Process Exits</a>	For a process that registers with the HA service, HAM starts the process when detecting the process exit.
<a href="#">HA Service of a Process That Restarts Frequently</a>	<ol style="list-style-type: none"> <li>1. Before patches are used for an upgrade, you can stop the HA service of a process that restarts frequently.</li> <li>2. After the patch-based upgrade is completed, confirm that no process restarts frequently and then start the HA service of the process that restarts frequently.</li> </ol>

#### 11.2.1 HA Service for Starting a Process When the Process Exits

##### Scenario

A process may exit in case of abnormalities. HAM can start this process.

##### Deployment

- On all devices in the system, run the HA service that starts a process when the process exits.

## 11.2.2 HA Service of a Process That Restarts Frequently

### Scenario

Originally, the purpose of importing the HA service of a process that restarts frequently is to clear frequent restart abnormalities of the process by restarting devices in some cases.

A process may restart under some abnormal conditions during a patch-based upgrade. If the device automatically restarts, traffic interruption can be caused. Some users desire to configure CLI commands to enable/disable the HA service of a process that restarts frequently.

If the HA service of a process that restarts frequently is disabled by a command, frequent restart abnormalities of some processes may not be cleared because the device does not restart automatically, resulting in a longer failure time.

### Deployment

- On all devices in the system, run the HA service of a process that restarts frequently. Use CLI commands on the master device to enable/disable this service and synchronize the service status to other non-master devices.

## 11.3 Features

### Basic Concepts

#### HAM

The HAM provides a high availability service for user processes.

### Overview

Feature	Description
HAM	Includes the HA service that starts a process when the process exits and the HA service of a process that restarts frequently.

### 11.3.1 HAM

A process may exit under some abnormal conditions. If the process is not started, some services will become unavailable. HAM can start the process in such circumstances, thereby restoring services.

### Working Principle

HAM perceives the exit of a process by listening to kernel advertisements and starts the process to restore services. If a process exits five times in two minutes, the HAM tries to start the process five minutes later. If two prompts, asking the HAM to start a process five minutes later, are displayed within ten minutes, it is deemed that services cannot be restored and the device needs to be restarted to restore the services.

## 11.4 Configuration

Configuration	Description and Command
---------------	-------------------------

<a href="#">Enabling and Disabling the HA Service of a Process That Restarts Frequently</a>	Disabling this HA service can lead to a longer failure time when a process frequently restarts. Therefore, you are not recommended to disable the configuration in scenarios other than patch-based upgrades.	
	<b>ham single-process-ha auto-restart enable</b>	Enables the HA service of a process that restarts frequently.

### 11.4.1 Enabling and Disabling the HA Service of a Process That Restarts Frequently

#### Configuration Effect

- Enable the HA service of a process that restarts frequently so that the system tries to automatically restart the device to restore services.

#### Notes

- It is not recommended to disable the HA service of a process that restarts frequently.

#### Configuration Steps

##### ▾ Enabling the HA Service of a Process That Restarts Frequently

- Optional. This feature can be used in a patch-based upgrade, to prevent device reset due to patch-based upgrade abnormalities.

<b>Command</b>	<b>ham single-process-ha auto-restart enable</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	The HA service of a process that restarts frequently is enabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This feature can be disabled before a patch-based upgrade. After the patch-based upgrade is completed, confirm that no process restarts frequently and then enable this feature.

#### Verification

Run the **show running-config | include ham** command to display the current HAM configuration.

<b>Command</b>	<b>show running-config   include ham</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Privileged EXEC mode
<b>Usage Guide</b>	This feature is enabled by default and the configuration is not displayed. If this feature is disabled, the configuration is displayed in the device running configuration.
<b>Command Presentation</b>	<pre>FS#show running-config   include HAM FS#</pre>

## Configuration Example

### ▾ Enabling and Disabling the HA Service of a Process That Restarts Frequently

<b>Scenario</b>	The master device for running CLI configuration commands exists.
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● In global configuration mode, run the <b>no ham single-process-ha auto-restart enable</b> command to disable the HA service of a process that restarts frequently.</li> <li>● In global configuration mode, run the <b>ham single-process-ha auto-restart enable</b> command to enable the HA service of a process that restarts frequently.</li> </ul>
<b>Master Device</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# no ham single-process-ha auto-restart enable FS(config)# show running-config   include ham no ham single-process-ha auto-restart enable FS(config)# ham single-process-ha auto-restart enable FS(config)# show running-config   include ham FS(config)#</pre>
<b>Verification</b>	Run the <b>show running-config   include ham</b> command to check whether the <b>ham single-process-ha auto-restart enable</b> configuration exists. The configuration is not displayed if this feature is enabled but displayed if this feature is disabled.
<b>Master Device</b>	<pre>FS#show running-config   include ham no ham single-process-ha auto-restart enable</pre>

### Common Errors

- N/A

## 11.5 Monitoring

### Displaying

Description	Command
Displays the current configuration.	<b>show running-config   include ham</b>

## 12 Configuring VAP (MLAG)

### 12.1 Overview

A Virtual Aggregate Port (VAP) and Multi-Chassis Link Aggregation (MLAG) are composed of two APs on two independent devices.

For other devices accessed through this VAP, the two devices can be considered as one logic device and the two APs of the VAP can be considered as one AP, thereby raising the link reliability from the board level to the device level. See the figure below.

Figure 12-1 VAP

Another similar technology is Virtual Switching Unit (VSU), which virtualizes multiple devices into one device. Compared with VSU, the VAP technology has the following advantages:

- Stacking is discarded and only layer-2 virtualization is required. The two devices are still independent of each other. The VAP reduces deployment difficulties and eliminates shortcomings brought by device stacking (for example, the software failure of the master device may make both devices unavailable).
- Devices can be upgraded independently without affecting the normal operation of the other device.

## 12.2 Applications

Application	Description
<a href="#">Connecting to an IP Network in Dual-Homing Mode</a>	The two devices of a VAP are connected to an IP network in uplink direction, to implement load balancing of network traffic.
<a href="#">Connecting to a Centralized VXLAN Network in Dual-Homing Mode</a>	The server connects to the network in VXLAN mode and the overlay gateway is configured on the core switch.

### 12.2.1 Connecting to an IP Network in Dual-Homing Mode

#### Scenario

The server connects to a network through VAP in dual-homing mode and the server gateway is configured on the VAP devices. The uplink traffic of the server is balanced to two access devices through APs. The downlink traffic is balanced to two access devices through ECMP and then locally forwarded to the server.

Figure 12-2 Connecting a VAP to an IP Network

**Remarks** AP1 and AP2 are added to the same VAP and are connected to layer-3 devices in uplink direction through routing interfaces and to a server or layer-2 switch in downlink direction.

**Deployment**

- Configure the same VAP domain on the two devices.
- Configure the same VAP for AP1 and AP2.

**12.2.2 Connecting to a VXLAN Network in Dual-Homing Mode**

**Scenario**

The server connects to a VXLAN network through VAP in dual-homing mode and the server gateway is configured on the core switch. The uplink traffic of the server is balanced to two access devices through APs. The downlink traffic is balanced to two access devices through ECMP and then locally forwarded to the server.

Figure 12-3 Connecting a VAP to a Centralized VXLAN Network

<b>Remarks</b>	AP1 and AP2 are added to the same VAP and are connected to a server or layer-2 switch in downlink direction.
----------------	--

### Deployment

- Configure the same VAP domain on the two devices.
- Configure the same VAP for AP1 and AP2.
- Configure VXLAN access and configure the gateway on the core switch.

## 12.3 Features

### Basic Concepts

#### ▾ VAP

APs on two independent devices form a VAP and only layer-2 APs are supported. Only one AP of a device can be added to the same VAP. One VAP can contain two APs at most.

#### ▾ VAP Member Interface

A member interface of a VAP is an AP added to the VAP. A local AP is called the VAP local member interface and a remote AP is called the VAP remote member interface.

#### ▾ Peer-link

The peer-link is a link between two devices of a VAP to synchronize data and transmit some traffic. The peer-link is also an AP. In order to enhance the reliability of the peer-link, you are recommended to configure the AP, to which the peer-link belongs, with two or more physical ports. For chassis devices, multiple physical ports should be deployed on different boards to reduce the impact of a board failure.

#### ▾ Peer-link Interface

A peer-link interface is a physical port of the peer-link.

#### ↘ VAP Domain

A VAP domain consists of two VAP devices connected through the peer-link. The two devices must share the same domain ID.

#### ↘ Dual-Active Detection Link

A dual-active detection link is used to detect the dual-active status of VAP devices when the peer-link fails.

#### ↘ HB Channel

A Hot-Backup (HB) channel is a TCP connection-based transmission channel established between two VAP devices. The VAP transmits and receives negotiation packets and data through this channel.

### Overview

Feature	Description
<u>VAP System Negotiation</u>	A VAP system is built on two devices via negotiation.
<u>Preferential Local Forwarding</u>	Traffic balanced to VAP devices is preferentially forwarded through the local member interface. When the local member interface malfunctions, the traffic is forwarded through the peer-link.
<u>Anti-Loop Mechanism</u>	When the VAP remote member interface works properly, the traffic of the peer-link is not forwarded to the local member interface. When the VAP remote member interface malfunctions, the traffic of the peer-link needs to be forwarded to the local member interface.

### 12.3.1 VAP System Negotiation

#### Working Principle

The basis of VAP application is that two devices pair with each other to form a system and provide inter-device aggregation capability. The process is as follows:

1. System pairing

After the domain ID, peer-link, and peer-link-based layer-3 channel are configured for the two VAP devices, the devices synchronize the domain ID with each other through the layer-3 channel. After receiving a synchronization message, a device checks whether the domain ID is consistent with its local domain ID. If yes, the two devices pair with each other successfully.

2. Master/slave negotiation

After successful pairing, the devices elect the master and slave roles based on their priority. The device with a higher priority is elected as the master device. If they share the same priority, the device with a smaller MAC address is elected as the master device.

 When both the master and slave devices work properly, packet forwarding is not different on them but different in failure scenarios. For example, when the peer-link is faulty, the VAP between the two devices fails. To avoid abnormal forwarding of traffic from access devices, the system shuts down service ports on the slave device and switches traffic to the master device.

3. Forwarding entry synchronization

After successful VAP negotiation, the two devices synchronize forwarding entries mutually such as MAC entries and ARP entries, to ensure active-active forwarding.

#### 4. Dual-active detection

After the VAP runs properly, heartbeat packets are sent periodically between the two devices to detect the availability of the dual-active link. When the dual-active link is detected to be faulty, if the peer-link works properly, a prompt is displayed, reminding users to check the dual-active link.

When the peer-link is faulty, the devices send dual-active detection packets to each other:

- If a device receives a detection response packet, dual master devices exist, and service interfaces (interfaces other than MGMT ports, peer-link interfaces, and stacked interfaces) on the slave device will be forced to enter error down state. To prevent an interface from entering error down state, you can configure it as an exceptional interface, for example, the interface for dual-active detection.
- If no detection response packet is received, the peer device is faulty.
  - If the local device is the slave device, it becomes the master device.
  - If the local device is the master device, it does not take any actions.

### 12.3.2 Preferential Local Forwarding

The peer-link can be understood as a backup link. When the network is stable and free of failures, service traffic is preferentially forwarded through the VAP local member interface. It should not be forwarded through the peer-link unless it is broadcast traffic. When the local member interface fails, service traffic needs to be forwarded through the peer-link. See the figure below.

Figure 12-4 Forwarding by the VAP Local Member Interface

Figure 12-5 Failure of the VAP Local Member Interface

### 12.3.3 Anti-Loop Mechanism

When an access device connects to a network through VAP in dual-homing mode, the two APs of the VAP are distributed on two independent devices, and independent forwarding by the two APs may result in a loop or receiving of double packets. VAP anti-loop rules are configured as follows:

1. When the VAP remote member interface works properly, traffic from the peer-link is not forwarded to the local member interface. See the figure below.

Figure 12-6 Peer-link Traffic Loop Prevention

2. When the VAP remote member interface fails, traffic from the peer-link needs to be forwarded to the local member interface. See the figure below.

Figure 12-7 Peer-link Traffic Loop Release

## 12.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of VAP	Mandatory:	
	<b>vap domain</b>	Configures a VAP domain.
	<b>peer-link</b>	Configures the peer-link.
	<b>vap</b>	Adds an AP to the VAP.
	<b>data-sync</b>	Configures a data synchronization channel.
	Optional:	
	<b>Priority</b>	Configures the priority.
Configuring Dual-Active Detection	Mandatory:	
	<b>peer-keepalive</b>	Configures a heartbeat link.
	Optional:	
	<b>peer-keepalive hold-time</b>	Configures the heartbeat holding time.
	<b>dual-active auto recovery</b>	Configures dual-active automatic recovery.
	<b>vap error-down except</b>	Configures an error down exceptional interface.
	<b>recover up-delay</b>	Configures the interface recovery delay.
Configuring the Domain Matching Delay	Optional:	
	<b>domain-match delay</b>	Configures the domain matching delay.
Configuring Convergence	Optional:	
	<b>fast-convergence</b>	Configures fast convergence.

### 12.4.1 Connecting to an IP Network in Dual-Homing Mode

#### Configuration Effect

- Two devices pair with each other to form a VAP system. The links of access devices are aggregated and connected to the VAP system in dual-homing mode.

- Traffic from VAP devices to access devices is first forwarded through the local VAP interface. When the local VAP interface fails, the traffic is forwarded to the VAP peer device.
- The server is connected to two independent network devices in dual-homing mode to form an active-active forwarding system. If a device malfunctions, user services can be still forwarded normally.

### Notes

- The server is connected to the network in dual-homing mode and interfaces on the two devices need to be added to the same VAP.
- It is recommended that the peer-link between the two devices be configured to allow all VLAN traffic to pass.
- You are advised to configure multiple physical links for the peer-link. For chassis devices, you should deploy physical links on different boards to avoid the impact of a board failure on the network.

### Configuration Steps

#### ▾ Configuring a VAP Domain

- Mandatory.
- Perform the configuration on both network devices that provide dual-homing access.

<b>Command</b>	<b>vap domain</b> <i>domain-id</i>
<b>Parameter Description</b>	<i>domain-id</i> : Indicates the domain ID. The value ranges from 1 to 255.
<b>Defaults</b>	No domain ID is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Only one domain ID can be configured on one device. VAP negotiation succeeds only when domain IDs on two devices are the same.

#### ▾ Configuring the Peer-link

- Mandatory.

<b>Command</b>	<b>peer-link</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	An AP is not the peer-link by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	When all member ports composing an AP of a VAP fail, traffic will be switched to the peer-link. When the remote member interface of a VAP works properly, traffic from the peer-link is not forwarded through the local member interface, in an effort to prevent loops. When the remote member interface of the VAP fails, traffic from the peer-link needs to be forwarded through the local member interface.

#### ▾ Adding an AP to the VAP

- Mandatory.
- One AP can be added to only one VAP and different APs on the same device must be added to different VAPs.

<b>Command</b>	<b>vap</b> <i>vap-id</i>
<b>Parameter</b>	<i>vap-id</i> : Indicates the ID of a VAP. The value ranges from 1 to 65,535.

<b>Description</b>	
<b>Defaults</b>	An AP is not added to a VAP by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The two APs on the two network devices that provide dual-homing access must be added to the same VAP.

### ↘ Configuring a Data Synchronization Channel

- Mandatory.

<b>Command</b>	<b>data-sync local</b> { <i>ip-address</i>   <i>ipv6-address</i> } <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }
<b>Parameter Description</b>	<b>local</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the local IP address. <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the peer IP address.
<b>Defaults</b>	No data synchronization channel is configured by default.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	Data is synchronized between VAP devices through a layer-3 IP network and this configuration is required on each VAP device. Either IPv4 or IPv6 addresses can be configured.

### ↘ Configuring a Heartbeat Link

- Mandatory.

<b>Command</b>	<b>peer-keepalive local</b> { <i>ip-address</i>   <i>ipv6-address</i> } <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }[ <i>interface-type</i> <i>interface-number</i> ]
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv4 address used for heartbeat detection. <i>ipv6-address</i> : Indicates the IPv6 address used for heartbeat detection. <i>interface-type</i> : Indicates the interface type. Only MGMT interfaces are supported. <i>interface-number</i> : Indicates the interface number. All MGMT interfaces are supported.
<b>Defaults</b>	No heartbeat link is configured by default.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	When the peer-link fails but the heartbeat link is normal, interfaces other than the MGMT interface, heartbeat interface, peer-link interface, and stacked interface on the slave device are triggered to enter the error down state. The interfaces return to the normal state after the peer-link is restored. Either IPv4 or IPv6 addresses can be configured.

### ↘ Configuring the Priority

- Optional.

<b>Command</b>	<b>priority</b> <i>priority</i>
<b>Parameter Description</b>	<i>priority</i> : Indicates the priority.
<b>Defaults</b>	The default priority is 4.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	VAP devices negotiate to determine their master/slave state after establishing communication. The master/slave negotiation rules are as follows: 1) The device with a higher priority is elected as the master device.

- 2) If the devices share the same priority, the device with a smaller MAC address is elected as the master device.

### ↘ Configuring the Heartbeat Holding Time

- Optional.

<b>Command</b>	<b>peer-keepalive hold-time</b> <i>interval</i>
<b>Parameter</b>	<i>interval</i> : Indicates the heartbeat holding time.
<b>Description</b>	
<b>Defaults</b>	The default heartbeat holding time is 3s.
<b>Command</b>	VAP domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	After the peer-link fails, the heartbeat link is retained for a period of time by default. After the time expires, if the heartbeat link is still normal, service interfaces on the slave device will enter error down state.

### ↘ Configuring the Interface Recovery Delay

- Optional.

<b>Command</b>	<b>recover up-delay</b> <i>interval</i> [ <b>none-vap</b> <i>none-vap-interval</i> ]
<b>Parameter</b>	<i>interval</i> : Indicates recovery delay of VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Description</b>	<i>none-vap-interval</i> : Indicates the recovery delay of non-VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Defaults</b>	The default recovery delay of VAP interfaces is 120s. There is no delay in the recovery of non-VAP interfaces by default.
<b>Command</b>	VAP configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	When the peer-link failure is rectified and devices are restarted, VAP interfaces are restored with a delay of 120s while non-VAP interfaces are restored without delay.

### ↘ Configuring an Exceptional Port for Dual-Active Detection

- Optional.

<b>Command</b>	<b>vap error-down except</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	No exceptional port for dual-active detection is configured by default.
<b>Command</b>	Interface configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	After the VAP detects the dual-active mode, it brings physical ports on the slave device to the error down state. To prevent an interface from entering error down state, you can run this command to configure it as an exceptional port. Within the interface recovery delay, physical ports are still in error down state.

### ↘ Configuring Fast Convergence Mode

- Optional.

<b>Command</b>	<b>fast-convergence</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	Fast convergence is enabled by default.
<b>Command</b>	VAP configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	After fast convergence is configured, the VAP fault convergence time is minimized. However, there may be considerable packets instantaneously, for example, flooding may occur.

### 📌 Configuring Dual-Active Automatic Recovery

- Optional.

<b>Command</b>	<b>dual-active auto recovery</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	Dual-active automatic recovery is not configured by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	<p>When the dual-active mode is detected, interfaces on the slave device are shut down. If dual-active automatic recovery is enabled, after the master device malfunctions, service interfaces on the slave device are restored.</p> <p>When the MGMT port is configured to detect the dual-active mode, dual-active automatic recovery is enabled automatically. When a service interface is configured to detect the dual-active mode, dual-active automatic recovery is disabled by default. You can determine whether to enable this function based on the deployment scenario:</p> <ol style="list-style-type: none"> <li>1) When the dual-active detection port is a port that directly connects two devices, configure the directly connected port as an exceptional port for dual-active detection (by running the <b>vap dad-down except</b> command), and then enable dual-active automatic recovery.</li> <li>2) If the dual-active detection port is not a directly connected port of two devices (for example, uplink port), dual-active automatic recovery cannot be enabled. Otherwise, repeated flapping will occur during dual-active detection.</li> </ol>

### Verification

- Run the **show vap [id]** command to display the two APs in the VAP. One is the local AP and the other is the remote AP.

<b>Command</b>	<b>show vap [id]</b>
<b>Parameter Description</b>	Indicates the ID of a VAP. The value ranges from 1 to 65,535.
<b>Command Mode</b>	Privileged EXEC mode, global configuration mode, and interface configuration mode
<b>Usage Guide</b>	This command is used to display information about a VAP.
<b>Command Presentation</b>	<pre> FS#show vap Vap domain: 245, Dev id: 2 Vap groups: 1  Vap 2   Local AggregatePort 2 is UP     TenGigabitEthernet 0/21 is UP   Remote AggregatePort 2 is UP     TenGigabitEthernet 1/0/21 is UP </pre>

**i** For details about fields shown by the **show** command, see the command manual of the corresponding feature.

**Configuration Example**

**Connecting to an IP Network in Dual-Homing Mode**

<p><b>Scenario</b> Figure 12-8</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure interface IP addresses for all devices (omitted).</li> <li>● Configure a dynamic routing protocol (such as OSPF) on TOR1, TOR2, and core switch (omitted).</li> <li>● Configure a VAP on TOR1 and TOR2.</li> </ul>

### Common Errors

N/A

### 12.4.2 Connecting to a Centralized VXLAN Network in Dual-Homing Mode

#### Configuration Effect

- Two devices pair with each other to form a VAP system. The links of access devices are aggregated and connected to the VAP system in dual-homing mode.
- Traffic from VAP devices to access devices is first forwarded through the local VAP interface. When the local VAP interface fails, the traffic is forwarded to the VAP peer device.
- Configure a centralized VXLAN, connect a server to a TOR switch, and configure the TOR switch to connect to the VXLAN active-active gateways in dual-homing mode. If one VXLAN gateway malfunctions, user services can be still forwarded normally.

#### Notes

- The TOR switch is connected to core switches in dual-homing mode and APs on the two core switches need to be added to the same VAP.
- It is recommended that the peer-link between the two devices be configured as a trunk link to allow all VLAN traffic to pass.
- You are advised to configure multiple physical links for the peer-link. For chassis devices, you should deploy physical links on different boards to avoid the impact of a board failure on the network.

#### Configuration Steps

##### 📌 Configuring a VAP Domain

- Mandatory.
- Perform the configuration on both network devices that provide dual-homing access.

<b>Command</b>	<b>vap domain</b> <i>domain-id</i>
<b>Parameter Description</b>	<i>domain-id</i> : Indicates the domain ID. The value ranges from 1 to 255.
<b>Defaults</b>	No domain ID is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Only one domain ID can be configured on one device. VAP negotiation succeeds only when domain IDs on two devices are the same.

### ▾ Configuring the Peer-link

- Mandatory.

<b>Command</b>	<b>peer-link</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	An AP is not the peer-link by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	When all member ports composing an AP of a VAP fail, traffic will be switched to the peer-link. When the remote member interface of a VAP works properly, traffic from the peer-link is not forwarded through the local member interface, in an effort to prevent loops. When the remote member interface of the VAP fails, traffic from the peer-link needs to be forwarded through the local member interface.

### ▾ Adding an AP to the VAP

- Mandatory.
- One AP can be added to only one VAP and different APs on the same device must be added to different VAPs.

<b>Command</b>	<b>vap</b> <i>vap-id</i>
<b>Parameter Description</b>	<i>vap-id</i> : Indicates the ID of a VAP. The value ranges from 1 to 65,535.
<b>Defaults</b>	An AP is not added to a VAP by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The two APs on the two network devices that provide dual-homing access must be added to the same VAP.

### ▾ Configuring a Data Synchronization Channel

- Mandatory.

<b>Command</b>	<b>data-sync local</b> { <i>ip-address</i>   <i>ipv6-address</i> } <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }
<b>Parameter Description</b>	<b>local</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the local IP address. <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the peer IP address.
<b>Defaults</b>	No data synchronization channel is configured by default.
<b>Command</b>	VAP domain configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	Data is synchronized between VAP devices through a layer-3 IP network and this configuration is required on each VAP device. Either IPv4 or IPv6 addresses can be configured.

### ▾ Configuring a Heartbeat Link

- Mandatory.

<b>Command</b>	<b>peer-keepalive local</b> { <i>ip-address ipv6-address</i> } <b>peer</b> { <i>ip-address ipv6-address</i> } [ <i>interface-type interface-number</i> ]
<b>Parameter</b>	<i>ip-address</i> : Indicates the IPv4 address used for heartbeat detection.
<b>Description</b>	<i>ipv6-address</i> : Indicates the IPv6 address used for heartbeat detection. <i>interface-type</i> : Indicates the interface type. Only MGMT interfaces are supported. <i>interface-number</i> : Indicates the interface number. All MGMT interfaces are supported.
<b>Defaults</b>	No heartbeat link is configured by default.
<b>Command</b>	VAP domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	When the peer-link fails but the heartbeat link is normal, interfaces other than the MGMT interface, heartbeat interface, peer-link interface, and stacked interface on the slave device are triggered to enter the error down state. The interfaces return to the normal state after the peer-link is restored. Either IPv4 or IPv6 addresses can be configured.

### ▾ Configuring the Priority

- Optional.

<b>Command</b>	<b>priority</b> <i>priority</i>
<b>Parameter</b>	<i>priority</i> : Indicates the priority.
<b>Description</b>	
<b>Defaults</b>	The default priority is 4.
<b>Command</b>	VAP domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	VAP devices negotiate to determine their master/slave state after establishing communication. The master/slave negotiation rules are as follows: 3) The device with a higher priority is elected as the master device. 4) If the devices share the same priority, the device with a smaller MAC address is elected as the master device.

### ▾ Configuring the Heartbeat Holding Time

- Optional.

<b>Command</b>	<b>peer-keepalive hold-time</b> <i>interval</i>
<b>Parameter</b>	<i>interval</i> : Indicates the heartbeat holding time.
<b>Description</b>	
<b>Defaults</b>	The default heartbeat holding time is 3s.
<b>Command</b>	VAP domain configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	After the peer-link fails, the heartbeat link is retained for a period of time by default. After the time expires, if the heartbeat link is still normal, service interfaces on the slave device will enter error down state.

### ↘ Configuring the Interface Recovery Delay

- Optional.

<b>Command</b>	<b>recover up-delay</b> <i>interval</i> [ <b>none-vap</b> <i>none-vap-interva</i> ]
<b>Parameter</b>	<i>interval</i> : Indicates recovery delay of VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Description</b>	<i>none-vap-interval</i> : Indicates the recovery delay of non-VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Defaults</b>	The default recovery delay of VAP interfaces is 120s. There is no delay in the recovery of non-VAP interfaces by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	When the peer-link failure is rectified and devices are restarted, VAP interfaces are restored with a delay of 120s while non-VAP interfaces are restored without delay.

### ↘ Configuring an Exceptional Port for Dual-Active Detection

- Optional.

<b>Command</b>	<b>vap error-down except</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	No exceptional port for dual-active detection is configured by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After the VAP detects the dual-active mode, it brings physical ports on the slave device to the error down state. To prevent an interface from entering error down state, you can run this command to configure it as an exceptional port. Within the interface recovery delay, physical ports are still in error down state.

### ↘ Configuring Fast Convergence Mode

- Optional.

<b>Command</b>	<b>fast-convergence</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	Fast convergence is enabled by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	After fast convergence is configured, the VAP fault convergence time is minimized. However, there may be considerable packets instantaneously, for example, flooding may occur.

### ↘ Configuring Dual-Active Automatic Recovery

- Optional.

<b>Command</b>	<b>dual-active auto recovery</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	Dual-master automatic recovery is not configured by default.
<b>Command Mode</b>	VAP configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	<p>When the dual-active mode is detected, interfaces on the slave device are shut down. If dual-active automatic recovery is enabled, after the master device malfunctions, service interfaces on the slave device are restored.</p> <p>When the MGMT port is configured to detect the dual-active mode, dual-active automatic recovery is enabled automatically. When a service interface is configured to detect the dual-active mode, dual-active automatic recovery is disabled by default. You can determine whether to enable this function based on the deployment scenario:</p> <ol style="list-style-type: none"> <li>1) When the dual-active detection port is a port that directly connects two devices, configure the directly connected port as an exceptional port for dual-active detection (by running the <b>vap dad-down except</b> command), and then enable dual-active automatic recovery.</li> <li>2) If the dual-active detection port is not a directly connected port of two devices (for example, uplink port), dual-active automatic recovery cannot be enabled. Otherwise, repeated flapping will occur during dual-active detection.</li> </ol>

### Verification

- Run the **show vap [id]** command to display the two APs in the VAP. One is the local AP and the other is the remote AP.

<b>Command</b>	<b>show vap [id]</b>
<b>Parameter Description</b>	Indicates the ID of a VAP. The value ranges from 1 to 65,535.
<b>Command Mode</b>	Privileged EXEC mode, global configuration mode, and interface configuration mode
<b>Usage Guide</b>	This command is used to display information about a VAP.
<b>Command Presentation</b>	<pre> FS#show vap Vap domain: 245, Dev id: 2  Vap groups: 1  Vap 2   Local AggregatePort 2 is UP     TenGigabitEthernet 0/21 is UP   Remote AggregatePort 2 is UP     TenGigabitEthernet 1/0/21 is UP </pre>

-  For details about fields shown by the **show** command, see the command manual of the corresponding feature.

### Configuration Example

#### ↘ Connecting to a Centralized VXLAN Network in Dual-Homing Mode

<p><b>Scenario</b></p> <p>Figure 12-9</p>	 <p>The diagram illustrates a network topology with two core switches, Core 1 and Core 2, connected via a DAD Link (192.168.3.0/24) and a Peer Link (Te0/2). Core 1 is connected to TOR1, and Core 2 is connected to TOR2. TOR1 and TOR2 are connected to Servers.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure interface IP addresses for all devices (omitted).</li> <li>● Configure a centralized EVPN VXLAN on TOR1, Core1, and Core2 (omitted).</li> <li>● Configure an AP on TOR2 and configure TOR2 to connect to Core1 and Core2 in dual-homing mode (omitted).</li> <li>● Configure a VAP on Core1 and Core2.</li> </ul>
<p><b>Core1</b></p>	<pre> Core1# configure terminal Configure a layer-3 IP address for VAP data synchronization and a heartbeat layer-3 IP address. Core1(config)# int vlan 100 Core1(config-if-VLAN 100)# ip address 192.168.1.1/24 Core1(config-if-VLAN 100)# exit Core1(config)# int mgmt 0 Core1(config-if-Mgmt0)# ip address 192.168.2.1/24 Core1(config-if-Mgmt 0)# exit Configure a VAP domain, data synchronization channel, and heartbeat detection channel. Core1(config)# vap domain 1 Core1(config-vap)# data-sync local 192.168.1.1 peer 192.168.1.2 Core1(config-vap)# peer-keepalive local 192.168.2.1 peer 192.168.2.2 mgmt 0 Core1(config-vap)# exit Configure physical member ports for peer-link APs. Core1(config)# interface TenGigabitEthernet 0/4 Core1(config-if-TenGigabitEthernet 0/4)# port-group 1 Core1(config-if-TenGigabitEthernet 0/4)# exit Core1(config)# interface TenGigabitEthernet 0/5 </pre>

	<pre> Core1(config-if-TenGigabitEthernet 0/5)# port-group 1 Core1(config-if-TenGigabitEthernet 0/5)# exit Configure the peer-link. Core1(config)# interface AggregatePort 1 Core1(config-if-AggregatePort 1)# switchport mode trunk Core1(config-if-AggregatePort 1)# switchport tr allowed vlan all Core1(config-if-AggregatePort 1)# peer-link Core1(config-if-AggregatePort 1)# exit Adddownlinkinterface Te0/2toAP2andAP2toVAP2. Core1(config)# interface TenGigabitEthernet 0/2 Core1(config-if-TenGigabitEthernet 0/2)# port-group 2 Core1(config-if-TenGigabitEthernet 0/2)# exit Core1(config)# interface AggregatePort 2 Core1(config-if-AggregatePort 2)# switchport access vlan 2 Core1(config-if-AggregatePort 2)# vap 2 Core1(config-if-AggregatePort 2)# exit Configure an overlay router active-active gateway. Core1(config)# interface OverlayRouter 10 Core1(config-if-OverlayRouter 10)# ip address 30.30.2.1/24 Core1(config-if-OverlayRouter 10)# anycast-gateway Core1(config-if-OverlayRouter 10)# exit </pre>
<b>Core2</b>	<pre> Core2# configure terminal Configure a layer-3 IP address for VAP data synchronization and a heartbeat IP address. Core2(config)# int vlan 100 Core2(config-if-VLAN 100)# ip address 192.168.1.2/24 Core2(config-if-VLAN 100)# exit Core2(config)# int mgmt 0 Core2(config-if-Mgmt0)# ip address 192.168.2.2/24 Core2(config-if-Mgmt 0)# exit Configure a VAP data synchronization channel and heartbeat detection channel. Core2(config)# vap domain 1 Core2(config-vap)# data-sync local 192.168.1.2 peer 192.168.1.1 Core2(config-vap)# peer-keepalive local 192.168.2.2 peer 192.168.2.1 mgmt 0 Core2(config-vap)# exit </pre>

	<p>Configure physical member ports for peer-link APs.</p> <pre>Core2(config)# interface TenGigabitEthernet 0/4 Core2(config-if-TenGigabitEthernet 0/4)# port-group 1 Core2(config-if-TenGigabitEthernet 0/4)# exit Core2(config)# interface TenGigabitEthernet 0/5 Core2(config-if-TenGigabitEthernet 0/5)# port-group 1 Core2(config-if-TenGigabitEthernet 0/5)# exit</pre> <p>Configure the peer-link.</p> <pre>Core2(config)# interface AggregatePort 1 Core2(config-if-AggregatePort 1)# switchport mode trunk Core2(config-if-AggregatePort 1)# switchport tr allowed vlan all Core2(config-if-AggregatePort 1)# peer-link Core2(config-if-AggregatePort 1)# exit</pre> <p>Adddownlinkinterface Te0/2toAP2andAP2toVAP2.</p> <pre>Core2(config)# interface TenGigabitEthernet 0/2 Core2(config-if-TenGigabitEthernet 0/2)# port-group 2 Core2(config-if-TenGigabitEthernet 0/2)# exit Core2(config)# interface AggregatePort 2 Core2(config-if-AggregatePort 2)# switchport access vlan 2 Core2(config-if-AggregatePort 2)# vap 2 Core2(config-if-AggregatePort 2)# exit</pre> <p>Configure an overlay router active-active gateway.</p> <pre>Core2(config)# interface OverlayRouter 10 Core2(config-if-OverlayRouter 10)# ip address 30.30.2.1/24 Core2(config-if-OverlayRouter 10)# anycast-gateway Core2(config-if-OverlayRouter 10)# exit</pre>
<b>Verification</b>	Run the <b>show vap</b> command to display the two APs in the same VAP. The APs should be in the normal state.
<b>Core1</b>	<pre>Core1# show vap Vap domain: 1, Dev id: 1 Vap groups: 2  Vap 2   LocalAggregatePort 2 is UP   TenGigabitEthernet 0/2 is UP</pre>

	Remote AggregatePort 2 is UP TenGigabitEthernet 0/2 is UP
<b>Core2</b>	Core2# show vap Vap domain: 1, Dev id: 2 Vap groups: 2  Vap 2 Local AggregatePort 2 is UP TenGigabitEthernet 0/2 is UP Remote AggregatePort 2 is UP TenGigabitEthernet 0/2 is UP

### Common Errors

N/A

### 12.4.3 Connecting to a Distributed VXLAN Network in Dual-Homing Mode

#### Configuration Effect

- Two devices pair with each other to form a VAP system. The links of access devices are aggregated and connected to the VAP system in dual-homing mode.
- Traffic from VAP devices to access devices is first forwarded through the local VAP interface. When the local VAP interface fails, the traffic is forwarded to the VAP peer device.
- Configure a distributed VXLAN and configure a server to connect to the VXLAN active-active gateways in dual-homing mode. If one VXLAN gateway malfunctions, user services can be still forwarded normally.

#### Notes

- The server is connected to the network in dual-homing mode and interfaces on the two TOR devices need to be added to the same VAP.
- It is recommended that the peer-link between the two devices be configured as a trunk link to allow all VLAN traffic to pass.
- You are advised to configure multiple physical links for the peer-link. For chassis devices, you should deploy physical links on different boards to avoid the impact of a board failure on the network.

#### Configuration Steps

##### 📌 Configuring a VAP Domain

- Mandatory.
- Perform the configuration on both network devices that provide dual-homing access.

<b>Command</b>	<b>vap domain</b> <i>domain-id</i>
<b>Parameter</b>	<i>domain-id</i> : Indicates the domain ID. The value ranges from 1 to 255.

<b>Description</b>	
<b>Defaults</b>	No domain ID is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Only one domain ID can be configured on one device. VAP negotiation succeeds only when domain IDs on two devices are the same.

### ▾ Configuring the Peer-link

- Mandatory.

<b>Command</b>	<b>peer-link</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	An AP is not the peer-link by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	When all member ports composing an AP of a VAP fail, traffic will be switched to the peer-link. When the remote member interface of a VAP works properly, traffic from the peer-link is not forwarded through the local member interface, in an effort to prevent loops. When the remote member interface of the VAP fails, traffic from the peer-link needs to be forwarded through the local member interface.

### ▾ Adding an AP to the VAP

- Mandatory.
- One AP can be added to only one VAP and different APs on the same device must be added to different VAPs.

<b>Command</b>	<b>vap <i>vap-id</i></b>
<b>Parameter Description</b>	<i>vap-id</i> : Indicates the ID of a VAP. The value ranges from 1 to 65,535.
<b>Defaults</b>	An AP is not added to a VAP by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The two APs on the two network devices that provide dual-homing access must be added to the same VAP.

### ▾ Configuring a Data Synchronization Channel

- Mandatory.

<b>Command</b>	<b>data-sync local { <i>ip-address</i>   <i>ipv6-address</i> } peer { <i>ip-address</i>   <i>ipv6-address</i> }</b>
<b>Parameter Description</b>	<b>local</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the local IP address. <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> }: Indicates the peer IP address.
<b>Defaults</b>	No data synchronization channel is configured by default.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	Data is synchronized between VAP devices through a layer-3 IP network and this configuration is required on each VAP device. Either IPv4 or IPv6 addresses can be configured.

### ▾ Configuring a Heartbeat Link

- Mandatory.

<b>Command</b>	<b>peer-keepalive local</b> { <i>ip-address</i>   <i>ipv6-address</i> } <b>peer</b> { <i>ip-address</i>   <i>ipv6-address</i> } [ <i>interface-type</i> <i>interface-number</i> ]
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv4 address used for heartbeat detection. <i>ipv6-address</i> : Indicates the IPv6 address used for heartbeat detection. <i>interface-type</i> : Indicates the interface type. Only MGMT interfaces are supported. <i>interface-number</i> : Indicates the interface number. All MGMT interfaces are supported.
<b>Defaults</b>	No heartbeat link is configured by default.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	When the peer-link fails but the heartbeat link is normal, interfaces other than the MGMT interface, heartbeat interface, peer-link interface, and stacked interface on the slave device are triggered to enter the error down state. The interfaces return to the normal state after the peer-link is restored. Either IPv4 or IPv6 addresses can be configured.

### ▾ Configuring the Priority

- Optional.

<b>Command</b>	<b>priority</b> <i>priority</i>
<b>Parameter Description</b>	<i>priority</i> : Indicates the priority.
<b>Defaults</b>	The default priority is 4.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	VAP devices negotiate to determine their master/slave state after establishing communication. The master/slave negotiation rules are as follows: 1) The device with a higher priority is elected as the master device. 2) If the devices share the same priority, the device with a smaller MAC address is elected as the master device.

### ▾ Configuring the Heartbeat Holding Time

- Optional.

<b>Command</b>	<b>peer-keepalive hold-time</b> <i>interval</i>
<b>Parameter Description</b>	<i>interval</i> : Indicates the heartbeat holding time.
<b>Defaults</b>	The default heartbeat holding time is 3s.
<b>Command Mode</b>	VAP domain configuration mode
<b>Usage Guide</b>	After the peer-link fails, the heartbeat link is retained for a period of time by default. After the time expires, if the heartbeat link is still normal, service interfaces on the slave device will enter error down state.

### ▾ Configuring the Interface Recovery Delay

- Optional.

<b>Command</b>	<b>recover up-delay</b> <i>interval</i> [ <b>none-vap</b> <i>none-vap-interval</i> ]
----------------	--

<b>Parameter</b>	<i>interval</i> : Indicates recovery delay of VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Description</b>	<i>none-vap-interval</i> : Indicates the recovery delay of non-VAP interfaces, in seconds. The value ranges from 0 to 3,600.
<b>Defaults</b>	The default recovery delay of VAP interfaces is 120s. There is no delay in the recovery of non-VAP interfaces by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	When the peer-link failure is rectified and devices are restarted, VAP interfaces are restored with a delay of 120s while non-VAP interfaces are restored without delay.

### ↘ Configuring an Exceptional Port for Dual-Active Detection

- Optional.

<b>Command</b>	<b>vap error-down except</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	No exceptional port for dual-active detection is configured by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	After the VAP detects the dual-active mode, it brings physical ports on the slave device to the error down state. To prevent an interface from entering error down state, you can run this command to configure it as an exceptional port. Within the interface recovery delay, physical ports are still in error down state.

### ↘ Configuring Fast Convergence Mode

- Optional.

<b>Command</b>	<b>fast-convergence</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	Fast convergence is enabled by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	After fast convergence is configured, the VAP fault convergence time is minimized. However, there may be considerable packets instantaneously, for example, flooding may occur.

### ↘ Configuring Dual-Active Automatic Recovery

- Optional.

<b>Command</b>	<b>dual-active auto recovery</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	Dual-active automatic recovery is not configured by default.
<b>Command Mode</b>	VAP configuration mode
<b>Usage Guide</b>	When the dual-active mode is detected, interfaces on the slave device are shut down. If dual-active automatic recovery is enabled, after the master device malfunctions, service interfaces on the slave device are restored. When the MGMT port is configured to detect the dual-active mode, dual-active automatic recovery is enabled

	<p>automatically. When a service interface is configured to detect the dual-active mode, dual-active automatic recovery is disabled by default. You can determine whether to enable this function based on the deployment scenario:</p> <ol style="list-style-type: none"> <li>1) When the dual-active detection port is a port that directly connects two devices, configure the directly connected port as an exceptional port for dual-active detection (by running the <b>vap dad-down except</b> command), and then enable dual-active automatic recovery.</li> <li>2) If the dual-active detection port is not a directly connected port of two devices (for example, uplink port), dual-active automatic recovery cannot be enabled. Otherwise, repeated flapping will occur during dual-active detection.</li> </ol>
--	--

### Verification

- Run the **show vap [id]** command to display the two APs in the VAP. One is the local AP and the other is the remote AP.

<b>Command</b>	<b>show vap [id]</b>
<b>Parameter Description</b>	Indicates the ID of a VAP. The value ranges from 1 to 65,535.
<b>Command Mode</b>	Privileged EXEC mode, global configuration mode, and interface configuration mode
<b>Usage Guide</b>	This command is used to display information about a VAP.
<b>Command Presentation</b>	<pre> FS#show vap Vap domain: 245, Dev id: 2 Vap groups: 1  Vap 2   Local AggregatePort 2 is UP     TenGigabitEthernet 0/21 is UP   Remote AggregatePort 2 is UP     TenGigabitEthernet 1/0/21 is UP </pre>

- For details about fields shown by the **show** command, see the command manual of the corresponding feature.

### Configuration Example

#### ↘ Connecting to a Distributed VXLAN Network in Dual-Homing Mode

<p><b>Scenario</b> Figure 12-10</p>

# 1 Configuring SNMP

## 1.1 Overview

Simple Network Management Protocol (SNMP) became a network management standard RFC 1157 in August 1988. At present, because many vendors support SNMP, SNMP has in fact become a network management standard and is applicable to the environment where systems of multiple vendors are interconnected. By using SNMP, the network administrator can implement basic functions such as information query for network nodes, network configuration, fault locating, capacity planning, and network monitoring and management.

### 📄 SNMP Versions

Currently, the following SNMP versions are supported:

- SNMPv1: The first official version of SNMP, which is defined in RFC 1157.
- SNMPv2C: Community-based SNMPv2 management architecture, which is defined in RFC 1901.
- SNMPv3: SNMPv3 provides the following security features by identifying and encrypting data.
  7. Ensuring that data is not tampered during transmission.
  8. Ensuring that data is transmitted from legal data sources.
  9. Encrypting packets and ensuring data confidentiality.

### Protocols and Standards

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)

- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

## 1.2 Applications

Application	Description
<u>Managing Network Devices Based on SNMP</u>	Network devices are managed and monitored based on SNMP.

### 1.2.1 Managing Network Devices Based on SNMP

#### Scenario

Take the following figure as an example. Network device A is managed and monitored based on SNMP network manager.

Figure 1-1

<b>Remarks</b>	A is a network device that needs to be managed. PC is a network management station.
----------------	--

#### Deployment

The network management station is connected to the managed network devices. On the network management station, users access the Management Information Base (MIB) on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

## 1.3 Features

### Basic Concepts

SNMP is an application layer protocol that works in C/S mode. It consists of three parts:

- SNMP network manager
- SNMP agent
- MIB

Figure 1-2 shows the relationship between the network management system (NMS) and the network management agent.

➤ **SNMP Network Manager**

The SNMP network manager is a system that controls and monitors the network based on SNMP and is also called the NMS.

➤ **SNMP Agent**

The SNMP agent (hereinafter referred to as the agent) is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

➤ **MIB**

The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits may be used to uniquely identify a management unit system among network devices. The MIB is a collection of unit identifiers of network devices.

Figure 1- 3 Tree Hierarchical Structure

➤ **Operation Types**

Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

- Get-request: The NMS extracts one or more parameter values from the agent.

- Get-next-request: The NMS extracts the parameter value next to one or more parameters from the agent.
- Get-bulk: The NMS extracts a batch of parameter values from the agent.
- Set-request: The NMS sets one or more parameter values of the agent.
- Get-response: The agent returns one or more parameter values, which are the operations in response to the three operations performed by the agent on the NMS.
- Trap: The agent actively sends a message to notify the NMS of something that happens.

The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. (Note: SNMPv1 does not support the Get-bulk operation.) Figure 1-4 describes the operations.

Figure 1- 4 SNMP Packet Types

The three operations performed by the NMS on the agent and the response operations of the agent are based on UDP port 161. The trap operation performed by the agent is based on UDP port 162.

**Overview**

Feature	Description
<u>Basic SNMP Functions</u>	The SNMP agent is configured on network devices to implement basic functions such as information query for network nodes, network configuration, fault locating, and capacity planning.
<u>SNMPv1 and SNMPv2C</u>	SNMPv1 and SNMPv2C adopt the community-based security architecture, including authentication name and access permission.
<u>SNMPv3</u>	SNMPv3 redefines the SNMP architecture, namely, it enhances security functions, including the security model based on users and access control model based on views. The SNMPv3 architecture already includes all functions of SNMPv1 and SNMPv2C.

**1.3.1 Basic SNMP Functions**

**Working Principle**

**Working Process**

SNMP protocol interaction is response interaction (for exchange of packets, see Figure 1-4). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and

returns a Get-response. Sometimes, the agent actively sends a trap message and an Inform message to the NMS. The NMS does not need to respond to the trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

## Related Configuration

### ↘ Shielding or Disabling the SNMP Agent

By default, the SNMP function is enabled.

The **no snmp-server** command is used to disable the SNMP agent.

The **no enable service snmp-agent** command is used to directly disable all SNMP services.

### ↘ Setting Basic SNMP Parameters

By default, the system contact mode, system location, and device Network Element (NE) information are empty. The default serial number is 60FF60, the default maximum packet length is 1,572 bytes, and the default UDP port ID of the SNMP service is 161.

The **snmp-server contact** command is used to configure or delete the system contact mode.

The **snmp-server location** command is used to configure or delete the system location.

The **snmp-server chassis-id** command is used to configure the system serial number or restore the default value.

The **snmp-server packetsize** command is used to configure the maximum packet length of the agent or restore the default value.

The **snmp-server net-id** command is used to configure or delete the device NE information.

The **snmp-server udp-port** command is used to set the UDP port ID of the SNMP service or restore the default value.

By default, SNMPv3 is enabled, while SNMP v1 and SNMPv2c are disabled.

The **no snmp-server enable version [ v1 | v2c | v3 ]** command is used to disable a specified SNMP version.

### ↘ Configuring the SNMP Host Address

By default, no SNMP host is configured.

The **snmp-server host** command is used to configure the NMS host address to which the agent actively sends messages or to delete the specified SNMP host address. In the messages sent to the host, the SNMP version, receiving port, authentication name, or user can be bound. This command is used with the **snmp-server enable traps** command to actively send trap messages to the NMS.

### ↘ Setting Trap Message Parameters

By default, SNMP is not allowed to actively send a trap message to the NMS, the function of sending a Link Trap message on an interface is enabled, the function of sending a system reboot trap message is disabled, and a trap message does not carry any private field.

By default, the IP address of the interface where SNMP packets are sent is used as the source address.

By default, the length of a trap message queue is 10 and the interval for sending a trap message is 30s.

The **snmp-server enable traps** command is used to enable or disable the agent to actively send a trap message to the NMS.

The **snmp trap link-status** command is used to enable or disable the function of sending a Link Trap message on an interface.

The **snmp-server trap-source** command is used to specify the source address for sending messages or to restore the default value.

The **snmp-server queue-length** command is used to set the length of a trap message queue or to restore the default value.

The **snmp-server trap-timeout** command is used to set the interval for sending a trap message or to restore the default value.

The **snmp-server trap-format private** command is used to set or disable the function of carrying private fields in a trap message when the message is sent.

The **snmp-server system-shutdown** command is used to enable or disable the function of sending a system reboot trap message.

### 1.3.2 SNMPv1 and SNMPv2C

SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

#### Working Principle

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. The authentication name of the NMS must be the same as an authentication name defined in devices.

SNMPv2C adds the Get-bulk operation mechanism and can return more detailed error message types to the management workstation. The Get-bulk operation is performed to obtain all information from a table or obtain lots of data at a time, so as to reduce the number of request responses. The enhanced error handling capabilities of SNMPv2C include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for errors. Now, errors can be differentiated based on error codes. Because management workstations supporting SNMPv1 and SNMPv2C may exist on the network, the SNMP agent must be able to identify SNMPv1 and SNMPv2C packets and return packets of the corresponding versions.

#### Security

One authentication name has the following attributes:

- Read-only: Provides the read permission of all MIB variables for authorized management workstations.
- Read-write: Provide the read/write permission of all MIB variables for authorized management workstations.

#### Related Configuration

##### Setting Authentication Names and Access Permissions

The default access permission of all authentication names is read-only.

The **snmp-server community** command is used to configure or delete an authentication name and access permission.

This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.

### 1.3.3 SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2 into the SNMPv3 system.

#### Working Principle

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the User-based Security Model (USM). The security level of the NMS user must be the same as that of an SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the discover and report operation mechanisms. When the NMS does not know agent engine IDs, the NMS may first send a discover message to the agent and the agent returns a report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

## ▾ Security

- SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include: SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

SNMPv1 and SNMPv2C Security Models and Security Levels

Security Model	Security Level	Authentication	Encryption	Description
SNMPv1	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.
SNMPv2c	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.

SNMPv3 Security Model and Security Level

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	User name.	N/A	Data validity is confirmed through user name.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and data encryption mechanism based on CBC-DES are provided.

## ▾ Engine ID

An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, one SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must have a unique engine ID, that is, SnpEngineID.

An engine ID is an octet string that consists of 5 to 32 bytes. RFC3411 defines the format of an engine ID:

- The first four bytes indicate the private enterprise ID (allocated by IANA) of a vendor, which is expressed in hexadecimal.
- The fifth byte indicates remaining bytes:
- 0: Reserved.
- 1: The later four bytes indicate an IPv4 address.
- 2: The later 16 bytes indicate an IPv6 address.
- 3: The later six bytes indicate a MAC address.
- 4: Text consisting of 27 bytes, which is defined by the vendor.
- 5: Hexadecimal value consisting of 27 bytes, which is defined by the vendor.

- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

## Related Configuration

### ▾ Configuring an MIB View and a Group

By default, one view is configured and all MIB objects can be accessed.

By default, no user group is configured.

The **snmp-server view** command is used to configure or delete a view and the **snmp-server group** command is used to configure or delete a user group.

One or more instructions can be configured to specify different community names so that network devices can be managed by NMSs of different permissions.

### ▾ Configuring an SNMP User

By default, no user is configured.

The **snmp-server user** command is used to configure or delete a user.

The NMS can communicate with the agent by using only legal users.

An SNMPv3 user can specify the security level (whether authentication and encryption are required), authentication algorithm (MD5 or SHA), authentication password, encryption password (only DES is available currently), and encryption password.

## 1.4 Configuration

Configuration	Description and Command	
<a href="#">Configuring Basic SNMP Functions</a>	 (Mandatory) It is used to enable users to access the agent through the NMS.	
	<b>enable service snmp-agent</b>	Enables the agent function.
	<b>snmp-server community</b>	Sets an authentication name and access permission.
	<b>snmp-server user</b>	Configures an SNMP user.
	<b>snmp-server view</b>	Configures an SNMP view.
	<b>snmp-server group</b>	Configures an SNMP user group.
	<b>snmp-server authentication</b>	Configures the SNMP attack protection and detection function.
<a href="#">Enabling the Trap Function</a>	 (Optional) It is used to enable the agent to actively send a trap message to the NMS.	
	<b>snmp-server host</b>	Configures the NMS host address.
	<b>snmp-server enable traps</b>	Enables the agent to actively send a trap message to the NMS.
	<b>snmp trap link-status</b>	Enables the function of sending a Link Trap message on an interface.
	<b>snmp-server system-shutdown</b>	Enables the function of sending a system reboot

Configuration	Description and Command	
		trap message.
	<b>snmp-server trap-source</b>	Specifies the source address for sending a trap message.
	<b>snmp-server trap-format private</b>	Enables a trap message to carry private fields when the message is sent.
<u>Shielding the Agent Function</u>	 (Optional) It is used to shield the agent function when the agent service is not required.	
	<b>no snmp-server</b>	Shields the agent function.
<u>Setting SNMP Control Parameters</u>	 (Optional) It is used to set or modify SNMP control parameters.	
	<b>snmp-server contact</b>	Sets the device contact mode.
	<b>snmp-server location</b>	Sets the device location.
	<b>snmp-server chassis-id</b>	Sets the serial number of the device.
	<b>snmp-server net-id</b>	Sets NE information about the device.
	<b>snmp-server packet-size</b>	Modifies the maximum packet length.
	<b>snmp-server udp-port</b>	Modifies the UDP port ID of the SNMP service.
	<b>snmp-server queue-length</b>	Modifies the length of a trap message queue.
	<b>snmp-server trap-timeout</b>	Modifies the interval for sending a trap message.
	<b>no snmp-server enable version</b>	Disables a specified SNMP version.

#### 1.4.1 Configuring Basic SNMP Functions

##### Configuration Effect

Enable users to access the agent through the NMS.

##### Notes

- By default, no authentication name is set on network devices and SNMPv1 or SNMPv2C cannot be used to access the MIB of network devices. When an authentication name is set, if no access permission is specified, the default access permission is read-only.

##### Configuration Steps

###### ▾ Configuring an SNMP View

- Optional
- An SNMP view needs to be configured when the View-based Access Control Model (VACM) is used.

###### ▾ Configuring an SNMP User Group

- Optional
- An SNMP user group needs to be configured when the VACM is used.

###### ▾ Configuring an Authentication Name and Access Permission

- Mandatory
- An authentication name must be set on the agent when SNMPv1 and SNMPv2C are used to manage network devices.

### ✚ Configuring an SNMP User

- Mandatory
- A user must be set when SNMPv3 is used to manage network devices.

### ✚ Enabling the Agent Function

- Optional
- By default, the agent function is enabled. When the agent function needs to be enabled again after it is disabled, this command must be used.

#### Verification

Run the **show snmp** command to check the SNMP function on devices.

#### Related Commands

### ✚ Configuring an SNMP View

<b>Command</b>	<b>snmp-server view</b> <i>view-name oid-tree { include   exclude }</i>
<b>Parameter</b>	<i>view-name</i> : View name
<b>Description</b>	<i>oid-tree</i> : MIB objects associated with a view, which are displayed as an MIB subtree. <b>include</b> : Indicates that the MIB object subtree is included in the view. <b>exclude</b> : Indicates that the MIB object subtree is not included in the view.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Specify a view name and use it for view-based management.

### ✚ Configuring an SNMP User Group

<b>Command</b>	<b>snmp-server group</b> <i>groupname { v1   v2c   v3 { auth   noauth   priv } } [ read <i>readview</i> ] [ write <i>writeview</i> ] [ access { ipv6 <i>ipv6-aclname</i>   <i>aclnum</i>   <i>aclname</i> } ]</i>
<b>Parameter</b>	<b>v1   v2c   v3</b> : Specifies the SNMP version.
<b>Description</b>	<b>auth</b> : Messages sent by users in the group need to be verified but data confidentiality is not required. This configuration is valid for SNMPv3 only. <b>noauth</b> : Messages sent by users in the group do not need to be verified and data confidentiality is not required. This configuration is valid for SNMPv3 only. <b>priv</b> : Messages sent by users in the group need to be verified and confidentiality of transmitted data is required. This configuration is valid for SNMPv3 only. <i>readview</i> : Associates one read-only view. <i>writeview</i> : Associates one read/write view. <i>aclnum</i> : ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>aclname</i> : ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>ipv6-aclname</i> : IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
<b>Command</b>	Global configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	Associate certain users with a group and associate the group with a view. Users in a group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.

### 📌 Configuring an Authentication Name and Access Permission

<b>Command</b>	<b>snmp-server community</b> [ 0   7 ] <i>string</i> [ <b>view</b> <i>view-name</i> ] [ [ <b>ro</b>   <b>rw</b> ] [ <b>host</b> <i>ipaddr</i> ] ] [ <b>ipv6</b> <i>ipv6-aclname</i> ] [ <i>aclnum</i>   <i>aclname</i> ]
<b>Parameter Description</b>	<p>0: Indicates that the input community string is a plaintext string.</p> <p>7: Indicates that the input community string is a ciphertext string.</p> <p><i>string</i>: Community string, which is equivalent to the communication password between the NMS and the SNMP agent.</p> <p><i>view-name</i>: Specifies a view name for view-based management.</p> <p><b>ro</b>: Indicates that the NMS can only read variables of the MIB.</p> <p><b>Note</b>: The N-Series data centre switch version has stricter security requirements. As public is the accepted default password and is very insecure, it cannot be configured to RO read-only mode when the community name of the snmp is public.</p> <p><b>rw</b>: The NMS can read and write variables of the MIB.</p> <p><i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname</i>: ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipaddr</i>: Associates NMS addresses and specifies NMS addresses for accessing the MIB.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.</p> <p>To disable the SNMP agent function, run the <b>no snmp-server</b> command.</p>

### 📌 Configuring an SNMP User

<b>Command</b>	<b>snmp-server user</b> <i>username</i> <i>groupname</i> { <b>v1</b>   <b>v2c</b>   <b>v3</b> [ <b>encrypted</b> ] [ <b>auth</b> { <b>md5</b>   <b>sha</b> } <i>auth-password</i> ] [ <b>priv</b> <b>des56</b>   <b>priv-des56</b> ] } [ <b>access</b> { <b>ipv6</b> <i>ipv6-aclname</i>   <i>aclnum</i>   <i>aclname</i> } ]
----------------	---

<b>Parameter</b>	<i>username</i> : User name.
<b>Description</b>	<p><i>groupname</i>: Specifies the group name for a user.</p> <p><b>v1   v2c   v3</b>: Specifies the SNMP version. Only SNMPv3 supports later security parameters.</p> <p><b>encrypted</b>: The specified password input mode is ciphertext input. Otherwise, plaintext is used for input. If ciphertext input is selected, enter a key consisting of continuous hexadecimal digits. An MD5 protocol authentication key consists of 16 bytes and an SHA authentication protocol key consists of 20 bytes. Two characters stand for one byte. Encrypted keys are valid for this engine only.</p> <p><b>auth</b>: Specifies whether authentication is used.</p> <p><b>md5</b>: Specifies the MD5 authentication protocol. <b>sha</b> specifies the SHA authentication protocol.</p> <p><i>auth-password</i>: Configures a password string (not more than 32 characters) used by the authentication protocol. The system converts the passwords into the corresponding authentication keys.</p> <p><b>priv</b>: Specifies whether confidentiality is used. <b>des56</b> specifies the use of the 56-bit DES encryption protocol.</p> <p><i>priv-password</i>: Configures a password string (not more than 32 characters) used for encryption. The system converts</p>

	<p>the password into the corresponding encryption key.</p> <p><i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname</i>: IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>Configure user information so that the NMS can communicate with the agent by using a valid user.</p> <p>For an SNMPv3 user, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (at present, only DES is available), and encryption password.</p>

↘ **Enabling the Agent Function**

<b>Command</b>	<b>enable service snmp-agent</b>
<b>Parameter Description</b>	
<b>Configuration mode</b>	Privileged mode.
<b>Usage Guide</b>	This command is used to enable the SNMP agent function of a device.

↘ **Displaying the SNMP Status Information**

<b>Command</b>	<b>show snmp [ mib   user   view   group   host   process-mib-time ]</b>
<b>Parameter Description</b>	<p><b>mib</b>: Displays information about the SNMP MIB supported in the system.</p> <p><b>user</b>: Displays information about an SNMP user.</p> <p><b>view</b>: Displays information about an SNMP view.</p> <p><b>group</b>: Displays information about an SNMP user group.</p> <p><b>host</b>: Displays information about user configuration.</p> <p><b>process-mib-time</b>: Displays the MIB node with the longest processing time.</p>
<b>Configuration mode</b>	Privileged mode.
<b>Usage Guide</b>	N/A

↘ **Configuration Example Configuring SNMP v1/2c**

<p><b>Scenario</b></p> <p><b>Figure 1- 5</b></p>	<pre> graph LR     Agent[Agent] --- Gi0/1[Gi0/1] --- NMS[NMS]     Agent --- IP1[IP:192.168.3.1/24]     NMS --- IP2[IP:192.168.3.2/24]     </pre> <ul style="list-style-type: none"> <li>● The NMS is connected to an agent through the Ethernet. The IP address of the agent is 192.168.3.1/24, and the IP address of the NMS is 192.168.3.2/24.</li> <li>● The NMS monitors and manages the agent through SNMP v1 or SNMP v2c.</li> </ul>
--	--

	<ul style="list-style-type: none"> <li>When the agent is faulty or an error occurs, the agent can actively reports the related information to the NMS.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure the SNMP basic information, including the version and community name.</li> <li>Allow the NMS (192.168.3.2/24) to send Trap messages.</li> <li>Configure the IP address of the agent, and set the IP address of the Gi0/1 interface to 192.168.3.1/24.</li> </ul>
<b>Agent</b>	<pre> FS(config)#snmp-server community public rw FS(config)#snmp-server host 192.168.3.2 traps version 2c public FS(config)#snmp-server enable traps FS(config)#interface gigabitEthernet 0/1 FS(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 FS(config-if-gigabitEthernet 0/1)#exit                     </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>Run the <b>show running-config</b> command to display configuration information of the device.</li> <li>Run the <b>show snmp host</b> command to display the host information configured by the user.</li> </ul>
<b>NMS</b>	<p>On the NMS that uses the SNMP v1/v2c, configure the read/write community name, timeout time, and retry times. You can use the NMS to query and configure the device.</p> <p> Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.</p>

📌 **Configuring SNMP v3 (Default View)**

<p><b>Scenario</b></p> <p><b>Figure 1- 6</b></p>	 <ul style="list-style-type: none"> <li>The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password.</li> <li>You can access all MIB nodes. ("read default write default" indicates that all MIB nodes can be accessed.)</li> <li>Network devices can actively send authentication and encryption messages to the NMS.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>Configure an MIB group. Create a group "g1", select the version "v3", set the security level to the authentication and encryption mode "priv", and configure permissions to read and write the view "default". "Default" indicates that all MIB nodes can be accessed.</li> <li>Configure an SNMP user. Create a user named "user1" under group "g1", select "v3" as the version, and set the authentication mode to "md5", authentication password to "123", encryption mode to "DES56", and encryption password to "321".</li> <li>Configure the SNMP host address. Set the host address to 192.168.3.2, select "3" as the version, set the security level to the authentication and encryption mode "priv", and associate the user name "user1". Enable the agent to actively send a trap message to the NMS.</li> </ul>

<p><b>Agent</b></p>	<ul style="list-style-type: none"> <li>● Configure the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.</li> </ul> <pre> FS(config)#snmp-server group g1 v3 priv read defaultwrite default FS(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321 FS(config)#snmp-server host 192.168.3.2traps version3priv user1 FS(config)#snmp-server enable traps FS(config)#interface gigabitEthernet 0/1 FS(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 FS(config-if-gigabitEthernet 0/1)#exit                     </pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>● Run the <b>show running-config</b> command to display configuration information of the device.</li> <li>● Run the <b>show snmp user</b> command to display the SNMP user.</li> <li>● Run the <b>show snmp view</b> command to display the SNMP view.</li> <li>● Run the <b>show snmp group</b> command to display the SNMP group.</li> <li>● Run the <b>show snmp host</b> command to display the host information configured by the user.</li> <li>● Install MIB-Browser.</li> </ul>
<p><b>NMS</b></p>	<p>SNMP v3 adopts the authentication and encryption security mechanisms. On the NMS, configure the user name, and select a security level. Based on the selected security level, configure the authentication mode, authentication password, encryption mode, and encryption password. In addition, configure the timeout time and retry times. You can use the NMS to query and configure the device. For details about the configuration, see Figure 1-7.</p> <p> Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.</p>

▾ **Configuring SNMPv3 Configuration (Specified View)**

<p><b>Scenario</b> Figure 1- 7</p>	<div style="text-align: center;"> </div> <ul style="list-style-type: none"> <li>● The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password.</li> <li>● Network devices can control the operation permission of users to access MIB objects. For example, the user named user1 can read MIB objects under the system node (1.3.6.1.2.1.1) and can only write MIB objects under the SysContact node (1.3.6.1.2.1.1.4.0).</li> <li>● Network devices can actively send authentication and encryption messages to the NMS.</li> </ul>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure a MIB view and a MIB group. Create a MIB view "view1", which includes the associated MIB object (1.3.6.1.2.1.1); then create a MIB view "view2", which includes the associated MIB object (1.3.6.1.2.1.1.4.0). Create a group "g1", select the version "v3", set the security level to the authentication and encryption mode "priv", and configure permissions to read the view "view1" and write the view "view2".</li> <li>● Configure an SNMP user. Create a user named "user1" under group "g1", select "v3" as the version, and set the authentication mode to "md5", authentication password to "123", encryption mode to "DES56", and encryption password to "321".</li> <li>● Configure the SNMP host address. Set the host address to 192.168.3.2, select "3" as the version, set the security level to the authentication and encryption mode "priv", and associate the username "user1". Enable the agent to actively send a trap message to the NMS.</li> <li>● Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.</li> </ul>

**1.4.2 Enabling the Trap Function**

**Configuration Effect**

Enable the agent to actively send a trap message to the NMS.

**Notes**

N/A

## Configuration Steps

### ▾ Configuring the SNMP Host Address

- Optional
- Configure the host address of the NMS when the agent is required to actively send messages.

### ▾ Enabling the Agent to Actively Send a Trap Message to the NMS

- Optional
- Configure this item on the agent when the agent is required to actively send a trap message to the NMS.

### ▾ Enabling the Function of Sending a Link Trap Message on an Interface

- Optional
- Configure this item on the agent when a link trap message needs to be sent on an interface.

### ▾ Enabling the Function of Sending a System Reboot Trap Message

- Optional
- Configure this item on the agent when the FSOS system is required to send a trap message to the NMS to notify system reboot before reloading or reboot of the device.

### ▾ Specifying the Source Address for Sending a Trap Message

- Optional
- Configure this item on the agent when it is required to permanently use a local IP address as the source SNMP address to facilitate management.

### ▾ Enabling a Trap Message to Carry Private Fields when the Message Is Sent

- Optional
- Configure this item on the agent when private fields need to be carried in a trap message.

## Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

## Related Commands

### ▾ Setting the NMS Host Address

<b>Command</b>	<b>snmp-server host</b> [ <b>oob</b> ] { <i>host-addr</i>   <b>ipv6</b> <i>ipv6-addr</i>   <b>domain</b> <i>domain-name</i> } [ <b>vrf</b> <i>vrfname</i> ] [ <b>traps</b>   <b>informs</b> ] [ <b>version</b> { <b>1</b>   <b>2c</b>   <b>3</b> { <b>auth</b>   <b>noauth</b>   <b>priv</b> } ] <i>community-string</i> [ <b>udp-port</b> <i>port-num</i> ] [ <i>notification-type</i> ]
<b>Parameter Description</b>	<p><b>oob</b>: Configures Out-Of-Band (OOB) communication for the alarm server (that is, information is sent to the alarm server through the MGMT interface).</p> <p><i>host-addr</i>: Address of the SNMP host.</p> <p><i>ipv6-addr</i>: (IPv6) address of the SNMP host.</p> <p><i>domain-name</i>: Domain name of the SNMP host.</p> <p><i>vrfname</i>: Configures a VRF forwarding table name.</p>

	<p><b>traps   informs:</b> Configures the host to send a trap message or an inform message.</p> <p><b>version:</b> SNMP version, which can be set to <b>V1</b>, <b>V2C</b>, or <b>V3</b>.</p> <p><b>auth   noauth   priv:</b> Sets the security level of V3 users.</p> <p><b>community-string:</b> Community string or user name (V3).</p> <p><b>port-num:</b> Configures the port ID of the SNMP host.</p> <p><b>notification-type:</b> Type of trap messages that are actively sent, for example, snmp.</p> <p> If no trap type is specified, all trap messages are sent.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>This command is used with the <b>snmp-server enable traps</b> command to actively send trap messages to the NMS. You can configure different SNMP hosts to receive trap messages. A host can support different traps, ports, and VRF forwarding tables. If the same host is configured (the port and VRF configuration are the same), the last configuration is combined with the previous configurations, that is, to send different trap messages to the same host, configure one type of trap messages each time. These configurations are finally combined.</p> <p> In this command, the <b>via</b> parameter can be specified only when the <b>oob</b> parameter is enabled. In addition, the <b>vrf</b> parameter cannot be used.</p>

#### ✎ Enabling the Agent to Actively Send a Trap Message to the NMS

<b>Command</b>	<b>snmp-server enable traps</b> [ <i>notification-type</i> ]
<b>Parameter Description</b>	<p><i>notification-type:</i> Enables trap notification for the corresponding events, including the following types:</p> <p>snmp: Enables trap notification for SNMP events.</p> <p>bgp: Enables trap notification for BGP events.</p> <p>bridge: Enables trap notification for bridge events.</p> <p>isis: Enables trap notification for ISIS events.</p> <p>mac-notification: Enables trap notification for MAC events.</p> <p>ospf: Enables trap notification for OSPF events.</p> <p>urpf: Enables trap notification for URPF events.</p> <p>vrrp: Enables trap notification for VRRP events.</p> <p>web-auth: Enables trap notification for Web authentication events.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command must be used with the <b>snmp-server host</b> command so that trap messages can be actively sent.

#### ✎ Enabling the Function of Sending a Link Trap Message on an Interface

<b>Command</b>	<b>snmp trap link-status</b>
<b>Parameter Description</b>	-
<b>Configuration mode</b>	Interface configuration mode
<b>Usage Guide</b>	For interfaces (Ethernet interface, AP interface, and SVI interface), when this function is enabled, the SNMP sends a Link Trap message if the link status on the interfaces changes. Otherwise, the SNMP does not send the message.

#### ✎ Enabling the Function of Sending a System Reboot Trap Message

<b>Command</b>	<b>snmp-server system-shutdown</b>
<b>Parameter Description</b>	-
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	When the function of notification upon SNMP system reboot is enabled, a trap message is sent to the NMS to notify system reboot before reloading or reboot of the device.

#### ▾ Specifying the Source Address for Sending a Trap Message

<b>Command</b>	<b>snmp-server trap-source <i>interface</i></b>
<b>Parameter Description</b>	<i>interface</i> : Used as the interface for the SNMP source address.
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	By default, the IP address of the interface where SNMP packets are sent is used as the source address. To facilitate management and identification, this command can be run to permanently use one local IP address as the source SNMP address.

#### ▾ Enabling a Trap message to Carry Private Fields when the Message Is Sent

<b>Command</b>	<b>snmp-server trap-format private</b>
<b>Parameter Description</b>	-
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	This command can be used to enable a trap message to carry private fields when the message is sent. At present, supported private fields include the alarm generation time. For the specific data types and data ranges of the fields, see FS-TRAP-FORMAT-MIB.mib.

### Configuration Example

#### ▾ Enabling the Trap Function

<b>Scenario</b> Figure 1- 8	 <p>The diagram illustrates a network setup where an Agent (represented by a switch icon) is connected to an NMS (represented by a server icon) via a Gi0/1 interface. The Agent's IP address is 192.168.3.1/24, and the NMS's IP address is 192.168.3.2/24.</p> <ul style="list-style-type: none"> <li>The NMS manages network devices (agents) based on the community authentication mode, and network devices can actively send messages to the NMS.</li> </ul>
<b>Configuration Steps</b>	<ol style="list-style-type: none"> <li>Perform configuration to enable the agent to actively send messages to the NMS. Set the SNMP host address to 192.168.3.2, the message format to Version2c, and the authentication name to user1. Enable the agent to actively send trap messages.</li> <li>Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.</li> </ol>

### 1.4.3 Shielding the Agent Function

#### Configuration Effect

Shield the agent function when the agent service is not required.

#### Notes

- Run the **no snmp-server** command to shield the SNMP agent function when the agent service is not required.
- Different from the shielding command, after the **no enable service snmp-agent** command is run, all SNMP services are directly disabled (that is, the SNMP agent function is disabled, no packet is received, and no response packet or trap packet is sent), but configuration information of the agent is not shielded.

#### Configuration Steps

##### ▾ Shielding the SNMP Agent Function for the Device

- Optional
- To shield the configuration of all SNMP agent services, use this configuration.

##### ▾ Disabling the SNMP Agent Function for the Device

- Optional
- To directly disable all services, use this configuration.

#### Verification

Run the **show service** command to check whether SNMP services are enabled or disabled.

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

#### Related Commands

Shielding the SNMP Agent Function for the Device

<b>Command</b>	<b>no snmp-server</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>By default, the SNMP agent function is disabled. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are set, the SNMP agent service is automatically enabled. The <b>enable service snmp-agent</b> command must also be run at the same time so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the <b>enable service snmp-agent</b> command is not run, the SNMP agent service does not take effect. Run the <b>no snmp-server</b> command to disable SNMP agent services of all versions supported by the device.</p> <p>After this command is run, all SNMP agent service configurations are shielded (that is, after the <b>show running-config</b> command is run, no configuration is displayed. Configurations are restored after the SNMP agent service is enabled again). After the <b>enable service snmp-agent</b> command is run, the SNMP agent configurations are not shielded.</p>

Disabling the SNMP Agent Function for the Device

<b>Command</b>	<b>no enable service snmp-agent</b>
<b>Parameter Description</b>	N/A
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	This command can be used to disable the SNMP service, but it will not shield SNMP agent parameters.

Configuration Example

Enabling the SNMP Service

<b>Scenario</b> Figure 1- 9	<p>After the SNMP service is enabled and the SNMP agent server is set, the NMS can access devices based on SNMP.</p>
<b>Configuration Steps</b>	<ol style="list-style-type: none"> <li>1. Enable the SNMP service.</li> <li>2. Set parameters for the SNMP agent server to make the SNMP service take effect.</li> </ol>
<b>A gent</b>	<code>FS(config)#enable service snmp-agent</code>
<b>Verification</b>	<ol style="list-style-type: none"> <li>1. Run the <b>show service</b> command to check whether the SNMP service is enabled or disabled.</li> </ol>
<b>Agent</b>	<pre>FS#show service web-server : disabled</pre>

```
web-server(https): disabled
snmp-agent      : enabled
ssh-server     : disabled
telnet-server  : enabled
```

### Common Errors

### 1.4.4 Setting SNMP Control Parameters

#### Configuration Effect

Set basic parameters of the SNMP agent, including the device contact mode, device location, serial number, and parameters for sending a trap message. By accessing the parameters, the NMS can obtain the contact person of the device and physical location of the device.

#### Notes

N/A

#### Configuration Steps

##### ▾ Setting the System Contact Mode

- Optional
- When the contact mode of the system needs to be modified, configure this item on the agent.

##### ▾ Setting the System Location

- Optional
- When the system location needs to be modified, configure this item on the agent.

##### ▾ Setting the System Serial Number

- Optional
- When the system serial number needs to be modified, configure this item on the agent.

##### ▾ Setting NE Information about the Device

- Optional
- When the NE code needs to be modified, configure this item on the agent.

##### ▾ Setting the Maximum Packet Length of the SNMP Agent

- Optional
- When the maximum packet length of the SNMP agent needs to be modified, configure this item on the agent.

##### ▾ Setting the UDP Port ID of the SNMP Service

- Optional

- When the UDP port ID of the SNMP service needs to be modified, configure this item on the agent.

#### ▾ Setting the Queue Length of Trap Messages

- Optional
- When the size of the message queue needs to be adjusted to control the message sending speed, configure this item on the agent.

#### ▾ Setting the Interval for Sending a Trap Message

- Optional
- When the interval for sending a trap message needs to be modified, configure this item on the agent.

#### ▾ Configuring SNMP Flow Control

- Optional
- If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

#### ▾ Configuring the SNMP Version

- Optional.
- SNMP contains three versions, that is, v1, v2C, and v3. If only a specific version is used for MIB interaction management in a user scenario, you can disable unused SNMP versions.

### Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

### Related Commands

#### ▾ Setting the System Contact Mode

<b>Command</b>	<b>snmp-server contact <i>text</i></b>
<b>Parameter Description</b>	<i>text</i> : String that describes the system contact mode.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ▾ Setting the System Location

<b>Command</b>	<b>snmp-server location <i>text</i></b>
<b>Parameter Description</b>	<i>text</i> : String that describes system information.
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Setting the System Serial Number

<b>Command</b>	<b>snmp-server chassis-id</b> <i>text</i>
<b>Parameter Description</b>	<i>text</i> : Text of the system serial number, which may be digits or characters.
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

### Setting NE Information about the Device

<b>Command</b>	<b>snmp-server net-id</b> <i>text</i>
<b>Parameter Description</b>	<i>text</i> : Text that is used to set the device NE code. The text is a string that consists of 1 to 255 characters that are case-sensitive and may include spaces.
<b>Configuration mode</b>	Global mode.
<b>Usage Guide</b>	Set the NE code of the device.

### Setting the Maximum Packet Length of the SNMP Agent

<b>Command</b>	<b>snmp-server packet-size</b> <i>byte-count</i>
<b>Parameter Description</b>	<i>byte-count</i> : Packet size, ranging from 484 bytes to 17,876 bytes.
<b>Configuration mode</b>	Global mode.
<b>Usage Guide</b>	N/A

### Setting the UDP Port ID of the SNMP Service

<b>Command</b>	<b>snmp-server udp-port</b> <i>port-num</i>
<b>Parameter Description</b>	<i>port-num</i> : Specifies the UDP port ID of the SNMP service, that is, the ID of the protocol port that receives SNMP packets.
<b>Configuration mode</b>	Global mode.
<b>Usage Guide</b>	Specify the protocol port ID for receiving SNMP packets.

### Setting the Length of a Trap Message Queue

<b>Command</b>	<b>snmp-server queue-length</b> <i>length</i>
<b>Parameter Description</b>	<i>length</i> : Queue length, ranging from 1 to 1,000.
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	Adjust the size of the message queue to control the message sending speed.

### Setting the Interval for Sending a Trap Message

<b>Command</b>	<b>snmp-server trap-timeout</b> <i>seconds</i>
<b>Parameter</b>	<i>seconds</i> : Interval (unit: second). The value range is 1 to 1,000.

<b>Description</b>	
<b>Configuration mode</b>	Global configuration mode
<b>Usage Guide</b>	Adjust the interval for sending a message to control the message sending speed.

### ▾ Configuring SNMP Flow Control

<b>Command</b>	<b>snmp-server flow-control pps [ count ]</b>
<b>Parameter Description</b>	<i>count</i> : Number of SNMP request packets processed per second. The value range is 50 to 65,535.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

### ▾ Configuring the SNMP Version

<b>Command</b>	<b>snmp-server enable version [ v1   v2c   v3 ]</b>
<b>Parameter Description</b>	v1, v2c, and v3 indicate three SNMP versions.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	If only one version is used for MIB interaction management in a user scenario, run this command to disable other versions.

## Configuration Example

### ▾ Setting SNMP Control Parameters

<b>Scenario</b> Figure 1- 10	 <p>The diagram illustrates a network setup where an Agent switch (left) is connected to an NMS server (right) via a Gi0/1 interface. ## 2 Configuring RMON

### 2.1 Overview

The Remote Network Monitoring (RMON) aims at resolving problems of managing local area networks (LANs) and remote sites by using one central point. In RMON, network monitoring data consists of a group of statistics and performance indicators, which can be used for monitoring the network utilization, so as to facilitate network planning, performance optimization, and network error diagnosis.

RMON is mainly used by a managing device to remotely monitor and manage managed devices.

#### Protocols and Standards

STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base

RFC4502: Remote Network Monitoring Management Information Base Version 2

RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)

RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules

RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms

RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions

RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services

RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks

RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros

RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

### 2.2 Applications

Application	Description
<a href="#">Collecting Statistics on Information of a Monitored Interface</a>	Applies four functions of RMON to an interface to monitor the network communication of the interface.

#### 2.2.1 Collecting Statistics on Information of a Monitored Interface

##### Scenario

The RMON Ethernet statistics function is used to monitor accumulated information of an interface, the history statistics function is used to monitor the packet count of an interface within each monitoring interval, and the alarm function is used to immediately acquire packet count exceptions of an interface. The following figure shows the networking topology.

Figure 2-1

## Deployment

Interface is monitored to accumulatively collect statistics on the packet count of the interface and collect statistics on the packet count and bandwidth utilization of the interface within the monitoring interval. If a packet count exception occurs on the interface, an alarm is reported to the network management system (NMS). The configuration key points are as follows:

- Configure the RMON Ethernet statistics function on interface.
- Configure the RMON history statistics function on interface.
- Configure the RMON alarm table and define RMON event processing actions in configuration mode. Monitored objects of alarms are the object identifier (OID) values of specific fields in the RMON Ethernet statistical table configured for interface.

## 2.3 Features

### Basic Concepts

RMON defines multiple RMON groups. FS products support the statistics group, history group, alarm group, and event group, which are described as follows:

#### ↘ Statistics Group

The statistics group is used to monitor and collect statistics on Ethernet interface traffic information, which is accumulated from the entry creation time to the current time. The statistical items include discarded data packets, broadcast data packets, cyclic redundancy check (CRC) errors, large and small blocks, and collisions. Statistical results are stored in the Ethernet statistical table.

#### ↘ History Group

The history group is used to periodically collect network traffic information. It records accumulated values of network traffic information and the bandwidth utilization within each interval, and saves them in the history control table. It includes two small groups:

- The HistoryControl group is used to set the sampling interval, sampling data source, and other control information.
- The EthernetHistory group provides administrators with historical data, including statistics on network segment traffic, error packets, broadcast packets, utilization, and number of collisions.

#### ↘ Alarm Group

The alarm group is used to monitor a specified Management Information Base (MIB) object. When the value of a MIB object exceeds the preset upper limit or is lower than the preset lower limit, an alarm is triggered and the alarm is processed as an event.

➤ **Event Group**

The event group is used to define the event processing mode. When a monitored MIB object meets alarm conditions, an event is triggered. An event can be processed in any of the following modes:

- none: No action is taken.
- log: Event-relevant information is recorded in the log record table so that administrators can view it at any time.
- snmp-trap: A trap message is transmitted to the NMS to notify the NMS of the event occurrence.
- log-and-trap: Event-relevant information is recorded in the log record table and a trap message is transmitted to the NMS.

**Working Principle**

RMON supports multiple monitors and two data collection methods. Method 1: A dedicated RMON probe is used to collect data and the NMS can directly acquire all information about the RMON MIB from the RMON probe. Method 2: RMON agents are built into network devices so that the devices have the RMON probe function. The NMS uses basic commands of the Simple Network Management Protocol (SNMP) to exchange data with the RMON agents and collect network management information. This method, however, is limited by device resources and information of only four groups rather than all data of the RMON MIB is acquired.

The following figure shows an example of communication between the NMS and RMON agents. The NMS, through the RMON agents running on devices, can acquire information about overall traffic, error statistics, and performance statistics of the network segment where a managed network device interface is, thereby implementing remote management of network devices.

Figure2-2

**Overview**

Feature	Description
<u>RMON Ethernet Statistics</u>	Collects statistics on the packet count, byte count, and other data of a monitored Ethernet interface accumulatively.
<u>RMON History Statistics</u>	Records the counts of packets, bytes, and other data communicated by an Ethernet interface within the configured interval and calculates the bandwidth utilization within the interval.
<u>RMON Alarm</u>	Samples values of monitored variables at intervals. The alarm table is used in combination with the event table. When the upper or lower limit is reached, a relevant event table is triggered to perform event processing or no processing is performed.

**2.3.1 RMON Ethernet Statistics**

**Working Principle**

The RMON Ethernet statistics function accumulatively collects statistics on network traffic information of an Ethernet interface from the entry creation time to the current time.

#### Related Configuration

##### ↘ Configuring RMON Statistical Entries

- The RMON Ethernet statistics function is disabled by default.
- Run the **rmon collection stats** command to create Ethernet statistical entries on a specified Ethernet interface.
- After statistical entries are successfully created on a specified interface, the statistics group collects statistics on the traffic information of the current interface. The statistical items are variables defined in the RMON Ethernet statistical table, and recorded information is the accumulated values of variables from the creation time of the RMON statistical table to the current time.

### 2.3.2 RMON History Statistics

#### Working Principle

The RMON history statistics function records accumulated statistics on traffic information of an Ethernet interface within each interval.

#### Related Configuration

##### ↘ Configuring RMON Historical Control Entries

- The RMON history statistics function is disabled by default.
- Run the **rmon collection history** command to create historical control entries on an Ethernet interface.
- The RMON history group collects statistics on variables defined in the RMON history table and records accumulated values of variables within each interval.

### 2.3.3 RMON Alarm

#### Working Principle

The RMON alarm function periodically monitors value changes of alarm variables. If the value of an alarm variable reaches the specified upper threshold or lower threshold, a corresponding event is triggered for processing, for example, a trap message is transmitted or one log Table entry record is generated. If a lower threshold or upper threshold is reached multiple times consecutively, only one corresponding event is triggered and another event is triggered till a reverse threshold is reached.

#### Related Configuration

##### ↘ Configuring the Event Table

- The RMON event group function is disabled by default.
- Run the **rmon event** command to configure the event table.

##### ↘ Configuring Alarm Entries

- The RMON alarm group function is disabled by default.
- Run the **rmon event** command to configure the event table and run the **rmon alarm** command to configure the RMON alarm table.

- The RMON alarm function is implemented by the alarm table and event table jointly. If a trap message needs to be transmitted to a managing device in the case of an alarm event, the SNMP agent must be correctly configured first. For the configuration of the SNMP agent, see the *Configuring SNMP*.
- If a configured alarm object is a field node in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function need to be configured on a monitored Ethernet interface first.

## 2.4 Configuration

Configuration	Description and Command	
<a href="#">Configuring RMON Ethernet Statistics</a>	 (Mandatory) It is used to accumulatively collect statistics on traffic information of an Ethernet interface.	
	<b>rmon collection stats</b>	Configures Ethernet statistical entries.
<a href="#">Configuring RMON History Statistics</a>	 (Mandatory) It is used to collect, at intervals, statistics on traffic information of an Ethernet interface and the bandwidth utilization within the interval.	
	<b>rmon collection history</b>	Configures historical control entries.
<a href="#">Configuring RMON Alarm</a>	 (Mandatory) It is used to monitor whether data changes of a variable is within the valid range.	
	<b>rmon event</b>	Configures event entries.
	<b>rmon alarm</b>	Configures alarm entries.

### 2.4.1 Configuring RMON Ethernet Statistics

#### Configuration Effect

Acquire accumulated statistics on traffic information of a monitored Ethernet interface from the entry creation time to the current time.

#### Notes

This function cannot be configured in batch interface configuration mode.

#### Configuration Steps

##### ▾ Configuring RMON Statistical Entries

- Mandatory.
- If statistics and monitoring are required for a specified interface, Ethernet statistical entries must be configured on this interface.

#### Verification

Run the **show rmon stats** command to display Ethernet statistics.

#### Related Commands

##### ▾ Configuring RMON Statistical Entries

<b>Command</b>	<b>rmon collection stats</b> <i>index</i> [ <b>owner</b> <i>ownername</i> ]
<b>Parameter</b>	<i>index</i> : Indicates the index number of a statistical entry, with the value ranging from 1 to 65,535.
<b>Description</b>	<b>owner</b> <i>ownername</i> : Indicates the entry creator, that is, <i>ownername</i> , which is a case-sensitive string of 1-63 characters.

<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The values of statistical entry parameters cannot be changed.

**Configuration Example**

▾ **Configuring RMON Ethernet Statistics**

<p><b>Scenario</b></p> <p>Figure 2-3</p>	
	<p>As shown in the preceding figure, the RMON agent is connected to the server, and the NMS requires the RMON statistics group to conduct performance statistics on received packets of interface Gi0/1. Administrators can view the statistics at any time to understand data about received packets of an interface and take measures in a timely manner to handle network exceptions.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure a statistical table instance on interface GigabitEthernet 0/1 to collect statistics on the traffic of this interface.</li> </ul>
<p><b>Agent</b></p>	<pre>FS# configure terminal FS (config)# interface gigabitEthernet 0/1 FS (config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin</pre>
<p><b>Verification</b></p>	<p>Run the <b>show rmon stats</b> command to display Ethernet statistics.</p>
<p><b>Agent</b></p>	<pre>FS# show rmon stats ether statistic table:     index = 1     interface = GigabitEthernet 0/1     owner = admin     status = 1     dropEvents = 0     octets = 25696     pkts = 293     broadcastPkts = 3     multiPkts = 0     crcAlignErrors = 0</pre>

### Common Errors

History control table entries are re-configured or configured history control table entries are modified.

### 2.4.3 Configuring RMON Alarm

#### Configuration Effect

Periodically monitor whether value changes of alarm variables are within the specified valid range.

#### Notes

If a trap message needs to be transmitted to a managing device when an alarm event is triggered, the SNMP agent must be correctly configured. For the configuration of the SNMP agent, see the *Configuring SNMP*.

If an alarm variable is a MIB variable defined in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function must be configured on the monitored Ethernet interface. Otherwise, an alarm table fails to be created.

#### Configuration Steps

##### ✚ Configuring Event Entries

- Mandatory.
- Complete the configuration in global configuration mode.

##### ✚ Configuring Alarm Entries

- Mandatory.
- Complete the configuration in global configuration mode.

#### Verification

- Run the **show rmon event** command to display the event table.
- Run the **show rmon alarm** command to display the alarm table.

#### Related Commands

### ↘ Configuring the Event Table

<b>Command</b>	<b>rmon event</b> <i>number</i> [ <b>log</b> ] [ <b>trap</b> <i>community</i> ] [ <b>description</b> <i>description-string</i> ] [ <b>owner</b> <i>ownername</i> ]
<b>Parameter Description</b>	<p><i>number</i>: Indicates the index number of an event table, with the value ranging from 1 to 65,535.</p> <p><b>log</b>: Indicates a log event. The system logs a triggered event.</p> <p><b>trap</b> <i>community</i>: Indicates a trap event. When an event is triggered, the system transmits a trap message with the community name of <i>community</i>.</p> <p><b>description</b> <i>description-string</i>: Sets the description information about an event, that is, <i>description-string</i>. The value is a string of 1-127 characters.</p> <p><b>owner</b> <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	The values of configured event entry parameters can be changed, including the event type, trap community name, event description, and event creator.

### ↘ Configuring the RMON Alarm Group

<b>Command</b>	<b>rmonalarm</b> <i>number</i> <i>variable</i> <i>interval</i> { <b>absolute</b>   <b>delta</b> } <b>rising-threshold</b> <i>value</i> [ <i>event-number</i> ] <b>falling-threshold</b> <i>value</i> [ <i>event-number</i> ] [ <b>owner</b> <i>ownername</i> ]
<b>Parameter Description</b>	<p><i>number</i>: Indicates the index number of an alarm entry, with the value ranging from 1 to 65,535.</p> <p><i>variable</i>: Indicates an alarm variable, which is a string of 1-255 characters and is represented in dotted format using the node OID (format: entry.integer.instance; example: 1.3.6.1.2.1.2.1.10.1).</p> <p><i>interval</i>: Indicates the sampling interval, with the unit of seconds and the value ranging from 1 to 2,147,483,647.</p> <p><b>absolute</b>: Indicates that the sampling type is absolute value sampling, that is, variable values are directly extracted when the sampling time is up.</p> <p><b>delta</b>: Indicates that the sampling type is changing value sampling, that is, changes in the variable values within the sampling interval are extracted when the sampling time is up.</p> <p><b>rising-threshold</b> <i>value</i>: Sets the upper limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p><i>event-number</i>: Indicates that an event with the event number of <i>event-number</i> is triggered when the upper limit or lower limit is reached.</p> <p><b>falling-threshold</b> <i>value</i>: Sets the lower limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p><b>owner</b> <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Values of configured alarm entry parameters can be changed, including alarm variables, sampling type, entry creator, sampling interval, upper/lower limit of the sampling quantity, and relevant trigger events.

### Configuration Example

#### ↘ Configuring RMON Alarm

<p><b>Scenario</b> <b>Figure 2-5</b></p>	
	<p>Assume that SNMPv1 runs on the NMS, the community name used for accessing the settings is public, with the attribute of read-write, and the IP address used by the NMS to receive trap messages is 3.3.3.3.</p> <p>Assume that the OID value of unknown protocol packets received by monitored interface GigabitEthernet0/1 is 1.3.6.1.2.1.2.2.1.15.3, the sampling mode is relative sampling, and the sampling interval is 60 seconds. When the relative sampling value is larger than 100 or lower than 10, event 1 and event 2 are triggered respectively. In event 1, a trap message is transmitted and the event is logged. In event 2, the event is only logged.</p> <p>The configuration of the RMON agent is completed on the terminal. The RMON agent is connected to the NMS and is connected to the server through interface Gi0/1. The RMON agent needs to monitor the count of unknown protocol packets received by interface Gi0/1. The sampling interval is 60 seconds. When the absolute sampling value is smaller than 10, the event is only logged. When the absolute sampling value is larger than 100, the event is logged and a trap message is transmitted to the NMS.</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure the host address for receiving trap messages.</li> <li>● Configure an event group to process alarm trigger.</li> <li>● Configure the alarm function.</li> </ul>

## Common Errors

- The entered OID of a monitored object is incorrect, the variable corresponding to the OID does not exist, or the type is not an integer or unsigned integer.
- The upper threshold is smaller than or equal to the lower threshold.

## 2.5 Monitoring

### Displaying

Description	Command
Displays all RMON configuration information.	<b>show rmon</b>
Displays the Ethernet statistical table.	<b>show rmon stats</b>
Displays the history control table.	<b>show rmon history</b>
Displays the alarm table.	<b>show rmon alarm</b>
Displays the event table.	<b>show rmon event</b>

## 3 Configuring NTP

### 3.1 Overview

The Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment.

Currently, FS devices can be used both as NTP clients and NTP servers. In other words, a FS device can synchronize time with a time server, and be used as a time server to provide time synchronization for other devices. When a FS device is used as a server, it supports only the unicast server mode.

### Protocols and Standards

- RFC 1305 : Network Time Protocol (Version 3)

### 3.2 Applications

Application	Description
<a href="#">Synchronizing Time Based on an External Reference Clock Source</a>	A device is used as a client that synchronizes time with an external clock source. After successful synchronization, it is used as a server to provide time synchronization for other devices.
<a href="#">Synchronizing Time Based on a Local Reference Clock Source</a>	A device uses a local clock as a reliable NTP reference clock source and is also used as a server to provide time synchronization for other devices.

#### 3.2.1 Synchronizing Time Based on an External Reference Clock Source

##### Scenario

As shown in Figure 3-1

- DEVICE-A is used as a reliable reference clock source to provide time synchronization for external devices.
- DEVICE-B specifies DEVICE-A as the NTP server and synchronizes time with DEVICE-A.
- After successful synchronization, DEVICE-B provides time synchronization for DEVICE-C.

Figure 3-1

### Deployment

Configure DEVICE-B to the NTP external reference clock mode.

### 3.2.2 Synchronizing Time Based on a Local Reference Clock Source

#### Scenario

As shown in Figure 3-2, DEVICE-B uses a local clock as the NTP reference clock source and provides time synchronization for DEVICE-C.

Figure 3-2

### Deployment

Configure DEVICE-B to the NTP local reference clock mode.

## 3.3 Features

### Basic Concepts

#### 📄 NTP Packet

As defined in RFC1305, NTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 3-3 shows the format of an NTP time synchronization packet.

Figure 3-3 Format of an NTP Time Synchronization Packet

0	7	15	23	31
LI	VN	Mode	Stratum	Poll Interval
Precision				
Root Delay (32-bit)				
Root Dispersion (32-bit)				
Reference Clock Identifier (32-bit)				
Reference Timestamp (64-bit)				
Originate Timestamp (64-bit)				
Receive Timestamp (64-bit)				
Transmit Timestamp (64-bit)				
Authenticator (optional 96-bit)				

- Leap Indicator(LI): indicates a 2-bit leap second indicator.
- i 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.
- Version Number(VN): indicates a 3-bit NTP version number. The current version number is 3.
- Mode: indicates a 3-bit NTP working mode.
- i 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.
- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master reference clock source; other values: indicate slave reference clock sources.
- Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
- Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.
- Root Delay: indicates the round-trip time to the master reference clock source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

**↘ NTP Server**

A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

➤ **NTP Client**

A device is used as an NTP client that synchronizes time with an NTP server in the network.

➤ **Stratum**

In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and soon. Therefore, clock sources with lower stratum values have higher clock precisions.

➤ **Hardware Clock**

A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

**Overview**

Feature	Description
<u>NTP Time Synchronization</u>	Network devices synchronize time with their servers or reliable clock sources to implement high-precision time correction.
<u>NTP Security Authentication</u>	The NTP packet encryption authentication is used to prevent unreliable clock sources from time synchronization interference on a device.
<u>NTP Access Control</u>	An Access Control List (ACL) is used to filter sources of received NTP packets.

**3.3.1 NTP Time Synchronization**

**Working Principle**

NTP time synchronization is implemented by interaction of NTP packets between a client and a server:

- The client sends a time synchronization packet to all servers every 64 seconds. After receiving response packets from the servers, the client filters and selects the response packets from all servers, and synchronizes time with an optimum server.
- After receiving the time synchronization request packet, a server uses the local clock as the reference source, and fills the local time information into the response packet to be sent to the client based on the protocol requirement.

Figure 3-4 shows the format of an NTP time synchronization packet.

Figure 3-4 Working Principle of NTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an NTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

10. A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
11. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
12. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
13. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula  $((T1-T0)+(T2-T3))/2$ .
- A obtains the packet round-trip delay of four seconds between A and B by using the formula  $(T3-T0)-(T2-T1)$ .

#### ▾ NTP Working Mode

- External clock reference mode

In this mode, a device is used as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server first and provide time synchronization for the clients after successful synchronization.

- Local clock reference mode

In this mode, a device uses the default local clock as the reliable clock source and provides time synchronization directly for other clients.

#### Related Configuration

##### ▾ Configuring an NTP Server

- The NTP function is disabled by default.
- Run the **ntp server** command to specify an NTP server (external clock reference source), which can enable NTP.
- After the configuration, the device works in the external clock reference mode.

##### ▾ Real-time Synchronization

- A device performs time synchronization every 64 seconds by default.

##### ▾ Updating a Hardware Clock

- By default, a device does not update synchronized time to the hardware clock.
- Run the **ntp update-calendar** command to enable a device to automatically update the hardware clock after successfully synchronizing time each time.

##### ▾ Configuring the NTP Master Clock

- By default, a device works in the external clock reference mode.
- Run the **ntp master** command to configure a device to the local clock reference mode.

### 3.3.2 NTP Security Authentication

To prevent malicious damage on an NTP server, NTP uses the authentication mechanism to check whether the time synchronization information is really from the announced server and check the information return path to provide an anti-interference protection mechanism.

#### Working Principle

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

#### Related Configuration

##### ✚ Configuring a Global Security Authentication Mechanism for NTP

- By default, no NTP security authentication mechanism is enabled.
- Run the **ntp authenticate** command to enable the NTP security authentication mechanism.

##### ✚ Configuring a Global Authentication Key for NTP

- By default, no global authentication key is configured.
- Run the **ntp authentication-key** command to enable an NTP global authentication key.

##### ✚ Configuring a Globally Trusted Key ID for NTP

- By default, no globally trusted key is configured.
- Run the **ntp trusted-key** command to configure a device as the reference clock source to provide a trusted key for time synchronization externally.

##### ✚ Configuring a Trusted Key ID for an External Reference Clock Source

- Run the **ntp server** command to specify an external reference source and the trusted key of this clock source as well.

### 3.3.3 NTP Access Control

#### Working Principle

Provide a minimum security measure by using an ACL.

#### Related Configuration

##### ✚ Configuring the Access Control Rights for NTP Services

- By default, there is no access control right for NTP.
- Run the **ntp access-group** command to configure the access control rights for NTP.

## 3.4 Configuration

Configuration	Description and Command
---------------	-------------------------

<u>Configuring Basic Functions of NTP</u>	 (Mandatory) It is used to enable NTP. After NTP is enabled, a device works in the external clock reference mode.	
	<b>ntp server</b>	Configures an NTP server.
	<b>ntp update-calendar</b>	Automatically updates a hardware clock.
	 (Optional) It is used to configure a device to the local clock reference mode.	
	<b>ntp master</b>	Configures the NTP master clock.
	 (Optional) It is used to disable NTP.	
	<b>no ntp</b>	Disables all functions of NTP and clears all NTP configurations.
	<b>ntp disable</b>	Disables receiving of NTP packets from a specified interface.
<u>Configuring NTP Security Authentication</u>	 (Optional) It is used to prevent unreliable clock sources from performing time synchronization interference on a device.	
	<b>ntp authenticate</b>	Enables a security authentication mechanism.
	<b>ntp authentication-key</b>	Configures a global authentication key.
	<b>ntp trusted-key</b>	Configures a trusted key for time synchronization.
	<b>ntp server</b>	Configures a trusted key for an external reference clock source.
<u>Configuring NTP Access Control</u>	 (Optional) It is used to filter the sources of received NTP packets.	
	<b>ntp access-group</b>	Configures the access control rights for NTP.

### 3.4.1 Configuring Basic Functions of NTP

#### Configuration Effect

##### ↘ External Clock Reference Mode

- Use a device as a client to synchronize time from an external reference clock source to the local clock.
- After the time synchronization is successful, use the device as a time synchronization server to provide time synchronization.

##### ↘ Local Clock Reference Mode

- Use the local clock of a device as the NTP reference clock source to provide time synchronization.

#### Notes

- In the client/server mode, a device can be used as a time synchronization server to provide time synchronization only after successfully synchronizing time with a reliable external clock source.
- Once the local clock reference mode is configured, the system will not synchronize time with a clock source with a higher stratum.

- Configuring a local clock as the master clock (especially when specifying a lower stratum) may overwrite an effective clock source. If this command is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the system time configuration section in the configuration guide.

## Configuration Steps

### ↘ Configuring an NTP Server

- (Mandatory) At least one external reference clock source must be specified (A maximum of 20 different external reference clock sources can be configured).
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server.

### ↘ Automatically Updating a Hardware Clock

- Optional.
- By default, the system updates only the system clock, but not the hardware clock after successful time synchronization.
- After this command is configured, the system automatically updates the hardware clock after successful time synchronization.

### ↘ Configuring the NTP Master Clock

- To switch a device to the local clock reference mode, run this command.

### ↘ Disabling NTP

- To disable NTP and clear NTP configurations, run the **no ntp** command.
- By default, all interfaces can receive NTP packets after NTP is enabled. To disable NTP for a specified interface, run the **ntp disable** command.

### ↘ Disabling the NTP Time Synchronization Service

- NTP works in client/server mode. After the NTP device synchronizes time from an external reliable clock source, it serves as the time server to provide the time synchronization service. If the device just needs to be served as an NTP client, configure the **ntp service disable** command to disable the NTP time synchronization service.

## Verification

- Run the **show ntp status** command to display the NTP configuration.
- Run the **show clock** command to check whether time synchronization is completed.

## Related Commands

### ↘ Configuring an NTP Server

<b>Command</b>	<b>ntpserver</b> [oob vrf vrf-name][ip-addr domain ip domain ipv6 domain][version version][source if-name][key keyid][prefer] [ via mgmt-name ]
<b>Parameter</b>	oob: Indicates whether a reference clock source is bound to the MGMT interface.

<b>Description</b>	<p><i>vrf-name</i>: Indicates the name of the VRF that is bound to the reference clock source.</p> <p><i>ip-addr</i>: Indicates the IPv4/IPv6 address of the reference clock source.</p> <p><i>domain</i>: Indicates the IPv4/IPv6 domain name of the reference clock source.</p> <p><i>version</i>: Indicates the NTP version number, ranging from 1 to 3.</p> <p><i>if-name</i>: Indicates the interface type, including AggregatePort, Dialer GigabitEthernet, Loopback, Multilink, Null, Tunnel, Virtual-ppp, Virtual-template and VLAN.</p> <p><i>keyid</i>: Indicates the key used for communicating with the reference clock source, ranging from 1 to 4294967295.</p> <p><b>prefer</b>: Indicates whether the reference clock source has a high priority.</p> <p><i>mgmt-name</i>: Specifies the egress management interface for packets in the oob mode.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>By default, no NTP server is configured. FS client system supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.</p> <p> If it is necessary to configure an authentication key, you must configure NTP security authentication before configuring an NTP server.</p> <p>The default version of NTP for communicating with a server is NTP version 3. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.</p>

#### ✎ Updating a Hardware Clock

<b>Command</b>	<b>ntp update-calendar</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ✎ Configuring a Local Reference Clock Source

<b>Command</b>	<b>ntp master[<i>stratum</i>]</b>
<b>Parameter Description</b>	<i>stratum</i> : specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ✎ Disabling NTP

<b>Command</b>	<b>no ntp</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command can be used to fast disable all functions of NTP and clear all NTP configurations.

▾ **Disabling Receiving of NTP Packets on an Interface**

<b>Command</b>	<b>ntp disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	N/A

▾ **Disabling the Time Synchronization Service Provided by NTP**

<b>Command</b>	<b>ntp service disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command disables the NTP time synchronization service. After this command is configured, external devices cannot be synchronized time from the NTP device (this command is supported only in some versions).

**Configuration Example**

▾ **External Clock Reference Mode of NTP**

<b>Scenario</b> Figure 3-5	
	<ul style="list-style-type: none"> <li>● DEVICE-B is configured to the NTP external clock reference mode.</li> <li>● DEVICE-A is used as the reference clock source of DEVICE-B.</li> <li>● DEVICE-C synchronizes time with DEVICE-B.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● DEVICE-A configures the local clock as the NTP reference clock source.</li> <li>● DEVICE-B configures DEVICE-A as the reference clock source.</li> <li>● DEVICE-C configures DEVICE-B as the reference clock source.</li> </ul>
<b>DEVICE-A</b>	<pre>A#configure terminal A(config)# ntp master A(config)#exit</pre>
<b>DEVICE-B</b>	<pre>B#configure terminal B(config)#ntp server 192.168.1.1 B(config)# exit</pre>
<b>DEVICE-C</b>	<pre>C#configure terminal</pre>

	<pre>C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show ntp status</b> command on DEVICE-B to display the NTP configuration.</li> <li>● DEVICE-B sends a time synchronization packet to 192.168.1.1 in order to synchronize time with DEVICE-A.</li> <li>● After successfully synchronizing time with DEVICE-A, DEVICE-B can respond to the time synchronization request from DEVICE-C.</li> <li>● Run the <b>show clock</b> command on DEVICE-B and DEVICE-C to check whether the time synchronization is successful.</li> </ul>

### Local Clock Reference Mode of NTP

<b>Scenario</b> <b>Figure 3-6</b>	
	<ul style="list-style-type: none"> <li>● DEVICE-B configures the local clock as the NTP reference clock source.</li> <li>● DEVICE-C synchronizes time with DEVICE-B.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● DEVICE-B configures the local clock as the NTP reference clock source.</li> <li>● DEVICE-C configures DEVICE-B as the reference clock source.</li> </ul>
<b>DEVICE-B</b>	<pre>B#configure terminal B(config)# ntp master B(config)# exit</pre>
<b>DEVICE-C</b>	<pre>C#configure terminal C(config)#ntp server 192.168.2.1 C(config)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show clock</b> command on DEVICE-C to check whether the time synchronization is successful.</li> </ul>

### 3.4.2 Configuring NTP Security Authentication

#### Configuration Effect

##### Synchronizing Time from a Trusted Reference Clock Source

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.

##### Providing Time Synchronization for a Trusted Device

Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

#### Notes

The authentication keys of the client and server must be the same.

#### Configuration Steps

### ✚ Configuring a Global Security Authentication Mechanism for NTP

- Mandatory.
- By default, a device disables the security authentication mechanism.

### ✚ Configuring a Global Authentication Key for NTP

- Mandatory.
- By default, a device is not configured with an authentication key.

### ✚ Configuring a Globally Trusted Key ID for NTP

- Optional.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID.
- Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.

### ✚ Configuring an Authentication Key ID for an External Reference Clock Source

- Optional.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID.
- Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.

#### Verification

- Run the **show run** command to verify the NTP configuration.
- Run the **show clock** command to check whether time is synchronized only with a trusted device.

#### Related Commands

### ✚ Enabling a Security Authentication Mechanism

<b>Command</b>	<b>ntp authenticate</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	By default, a client does not use a global security authentication mechanism. If no security authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication between the client and server.

### ✚ Configuring a Global Authentication Key

<b>Command</b>	<b>ntp authentication-key <i>key-id</i> md5 <i>key-string</i> [<i>enc-type</i>]</b>
<b>Parameter Description</b>	<i>key-id</i> : indicates the ID of a global authentication key, ranging from 1 to 4294967295. <i>key-string</i> : indicates a key string. <i>enc-type</i> : (optional) indicates whether an entered key is encrypted. 0 indicates no encryption, and 7 indicates simple

	encryption. The default setting is no encryption.
<b>Command</b>	Global configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	N/A

▾ **Configuring a Trusted Key for NTP**

<b>Command</b>	<b>ntp trusted-key</b> <i>key-id</i>
<b>Parameter Description</b>	<i>key-id</i> : Indicates the ID of a trusted key, ranging from 1 to 4294967295.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

▾ **Configuring a Trusted Key for an External Reference Clock Source**

Refer to the section "Related Commands".

**Configuration Example**

▾ **Security Authentication**

<b>Scenario</b> Figure 3-7	
	<ul style="list-style-type: none"> <li>● DEVICE-B is configured to the NTP client/server mode and provides NTP services requiring security authentication for DEVICE-C. The authentication key is "abcd".</li> <li>● DEVICE-A is used as the reference clock source of DEVICE-B.</li> <li>● DEVICE-C synchronizes time with DEVICE-B.</li> </ul>
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● DEVICE-B configures DEVICE-A as the reference clock source.</li> <li>● DEVICE-C configures DEVICE-B as the reference clock source.</li> </ul>
<b>DEVICE-B</b>	<pre> B#configure terminal B(config)#ntp authentication-key 1 md5 abcd B(config)# ntp trusted-key 1 B(config)# ntp server 192.168.1.1 B(config)# exit                     </pre>
<b>DEVICE-C</b>	<pre> C#configure terminal C(config)# ntp authentication-key 1 md5 abcd C(config)# ntp server 192.168.2.1 key 1 C(config)# exit                     </pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● DEVICE-B sends a time synchronization packet that carries authentication information to 192.168.1.1 in order to synchronize time with DEVICE-A.</li> </ul>

- Run the **show clock** command on DEVICE-B to check whether the time synchronization is successful.

### 3.4.3 Configuring NTP Access Control

#### Configuration Effect

Access control for NTP services provides a minimum security measure. A more secure method is to use an NTP authentication mechanism.

#### Notes

- Currently, the system does not support control query (used to control NTP servers by using network management devices, such as setting the leap second indicator or monitoring its working status). Though rule matching is implemented in the preceding sequence, no request related to control query is supported.
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.

#### Related Configuration

##### ▾ Configuring the Access Control Rights for NTP

- Optional.
- Run the **ntp access-group** command to configure the access control rights and a corresponding ACL for NTP.

#### Verification

Run the **show run** command to verify the NTP configuration.

#### Related Commands

##### ▾ Configuring the Access Control Rights for NTP Services

<b>Command</b>	<b>ntp access-group { peer   serve  serve-only   query-only }access-list-number   access-list-name</b>
<b>Parameter Description</b>	<p><b>peer</b>: allows time request and control query for local NTP services, and allows a local device to synchronize time with a remote system (full access rights).</p> <p><b>serve</b>: allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system.</p> <p><b>serve-only</b>: allows only time request for local NTP services.</p> <p><b>query-only</b>: allows only control query for local NTP services.</p> <p><i>access-list-number</i>: indicates the number of an IP ACL, ranging from 1 to 99 and from 1300 to 1999. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p> <p><i>access-list-name</i>: indicates the name of an IP ACL. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>Configure NTP access control rights.</p> <p>When an access request arrives, the NTP service matches rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is peer, serve, serve-only,</p>

	and query-only.
--	-----------------

### Configuration Example

#### ▾ Configuring NTP Access Control Rights

<b>Configuration Steps</b>	Allow only the device with the IP address of 192.168.1.1 to send a time synchronization request to a local device.
	<pre>FS(config)# access-list 1 permit 192.168.1.1 FS(config)# ntp access-group serve-only 1</pre>

## 3.5 Monitoring

### Displaying

Description	Command
<b>show ntp status</b>	Displays the current NTP information.

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
<b>debug ntp</b>	Enables debugging.
<b>no debug ntp</b>	Disables debugging.

## 4 Configuring SNTP

### 4.1 Overview

The Simple Network Time Protocol (SNTP) is a simplified version of Network Time Protocol (NTP), which is used to synchronize the clocks of computers on the Internet. SNTP is applied in scenarios where it is unnecessary to use all NTP functions.

NTP uses a complex algorithm and has higher requirements for the system whereas SNTP uses a simpler algorithm and provides higher performance. Generally, SNTP precision can reach about 1s, which meets the basic requirements of most scenarios. Since SNTP packets are the same as NTP packets, the SNTP client implemented on a device is fully compatible with an NTP server.

### Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

### 4.2 Applications

Application	Description
<u>Synchronizing Time with an NTP Server</u>	A device is used as a client to synchronize time with an NTP server.

### 4.2.1 Synchronizing Time with an NTP Server

#### Scenario

As shown in Figure 4-1, DEVICE-B uses a local clock as the NTP clock reference source and provides time synchronization for DEVICE-C. DEVICE-C is used as an SNTP client to synchronize time with DEVICE-B.

Figure 4-1

#### Deployment

- Specify DEVICE-B as the SNTP server of DEVICE-C.
- Enable SNTP for DEVICE-C.

### 4.3 Features

#### Basic Concepts

##### SNTP Packet

SNTPV4 is developed from NTP, which is intended to simplify the functions of NTP. It does not change the NTP specifications and the original implementation of NTP. The message format of SNTPV4 is the same as that of NTP defined in RFC1305, with only some data fields initialized into preset values.

As defined in RFC1305, SNTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 4-2 shows the format of an SNTP time synchronization packet.

Figure 4-2 Format of an SNTP Time Synchronization Packet

0	7	15	23	31
LI	VN	Mode	Stratum	Poll Interval
Precision				
Root Delay (32-bit)				
Root Dispersion (32-bit)				
Reference Clock Identifier (32-bit)				
Reference Timestamp (64-bit)				
Originate Timestamp (64-bit)				
Receive Timestamp (64-bit)				
Transmit Timestamp (64-bit)				
Authenticator (optional 96-bit)				

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

- i 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.
- Version Number(VN): indicates a 3-bit NTP/SNTP version number. The current version number is 3.
- Mode: indicates a 3-bit SNTP/NTP working mode.
- i 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.
- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master clock reference source; other values: indicate slave clock reference sources.
- Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
- Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.
- Root Delay: indicates the round-trip time to the master clock reference source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

**Overview**

Feature	Description
SNTP Time Synchronization	Synchronizes time from an SNTP/NTP server to a local device.

**4.3.1 SNTP Time Synchronization**

**Working Principle**

SNTP time synchronization is implemented by interaction of SNTP/NTP packets between a client and a server. The client sends a time synchronization packet to the server at intervals (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

Figure 4-3 shows the format of an SNTP time synchronization packet.

Figure 4-3 Working Principle of SNTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an SNTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

14. A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
15. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
16. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
17. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula  $((T1-T0)+(T2-T3))/2$ .
- A obtains the packet round-trip delay of four seconds between A and B by using the formula  $(T3-T0)-(T2-T1)$ .

### Related Configuration

#### ▾ Enabling SNTP

- SNTP is disabled by default.
- Run the **sntp enable** command to enable SNTP.

#### ▾ Configuring an SNTP Server

- By default, no SNTP server is configured.
- Run the **sntp server** command to specify an SNTP server.

#### ▾ Configuring the SNTP Time Synchronization Interval

- By default, the SNTP time synchronization interval is 1,800s.
- Run the **sntp interval** command to specify the time synchronization interval.

## 4.4 Configuration

Configuration	Description and Command	
<u>Configuring SNTP</u>	 (Mandatory) It is used to enable SNTP.	
	<b>sntp enable</b>	Enables SNTP.
	<b>sntp server</b>	Configures the IP address of an SNTP server.
	 (Optional) It is used to configure the SNTP time synchronization interval.	
	<b>sntp interval</b>	Configures the SNTP time synchronization interval.

### 4.4.1 Configuring SNTP

#### Configuration Effect

An SNTP client accesses an NTP server at fixed intervals to correct the clock regularly.

#### Notes

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

#### Configuration Steps

##### ▾ Enabling SNTP

- (Mandatory) SNTP is disabled by default.

##### ▾ Configuring the IP address of an SNTP Server

- (Mandatory) No SNTP/NTP server is configured by default.

##### ▾ Configuring the SNTP Time Synchronization Interval

- Optional.
- By default, a device synchronizes time every half an hour.

#### Verification

Run the **show sntp** command to display SNTP-related parameters.

#### Related Commands

##### ▾ Enabling SNTP

<b>Command</b>	<b>sntp enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	SNTP is disabled by default. Run the <b>no sntp enable</b> global configuration command to disable SNTP.

### ▾ Configuring the IP address of an SNTP/NTP Server

<b>Command</b>	<code>sntp server [ oob ] ip-address [ via mgmt-name ]</code>
<b>Parameter Description</b>	<i>ip-address</i> : indicates the IP address of an NTP/SNTP server. No NTP/SNTP server is configured by default.
	<i>oob</i> : indicates that the NTP/SNTP server supports an out-band management interface (interface of mgmt). <i>mgmt-name</i> : Specifies the egress management interface for packets in the oob mode.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Since SNTP is fully compatible with NTP, the server can be configured as a public NTP server on the Internet. Since SNTP packets are the same as NTP packets, the SNTP client is fully compatible with the NTP server. There are many NTP servers on the Internet. You can select an NTP server with a shorter delay as the SNTP server on your device.

### ▾ Configuring the SNTP Time Synchronization Interval

<b>Command</b>	<code>sntp interval seconds</code>
<b>Parameter Description</b>	<i>seconds</i> : Indicates the time synchronization interval, ranging from 60s to 65,535s. The default value is 1,800s.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Run this command to set the interval for an SNTP client to synchronize time with an NTP/SNTP server.  The interval configured here does not take effect immediately. To make it take effect immediately, run the <code>sntp enable</code> command.

### Configuration Example

#### ▾ SNTP Time Synchronization

<b>Scenario</b> Figure 4-4	
	<ul style="list-style-type: none"> <li>● DEVICE-B indicates an NTP server on the Internet.</li> <li>● DEVICE-C synchronizes time with DEVICE-B.</li> </ul>
<b>Configuration Steps</b>	Enable SNTP for DEVICE-C and configure DEVICE-B as an NTP server.
<b>DEVICE-C</b>	<pre>C#configure terminal C(config)# sntp server 192.168.2.1 C(config)# sntp enable C(config)# exit</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <code>show clock</code> command on DEVICE-C to check whether the time synchronization is successful.</li> <li>● Run the <code>show sntp</code> command on DEVICE-C to display the SNTP status and check whether the server is successfully configured.</li> </ul>

## 4.5 Monitoring

### Displaying

Description	Command
show snmp	Displays SNMP-related parameters.

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
debug snmp	Enables debugging.

## 5 Configuring SPAN-RSPAN

### 5.1 Overview

The Switched Port Analyzer (SPAN) is to copy packets of a specified port to another switch port that is connected to a network monitoring device, so as to achieve network monitoring and troubleshooting.

All input and output packets of a source port can be monitored through SPAN. For example, as shown in the following figure, all packets on Port 5 are mapped to Port 10, and the network analyzer connected to Port 10 receives all packets that pass through Port 5.

Figure 5-1 SPAN Configuration Instance

The SPAN function is mainly applied in network monitoring and troubleshooting scenarios, to monitor network information and rectify network faults.

The Remote SPAN (RSPAN), an extension to SPAN, is capable of remotely monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port. Users can observe data packets of the remote mirrored port by using an analyzer in the central equipment room.

The application scenarios of RSPAN are similar to those of SPAN. RSPAN allows users to conduct real-time data monitoring without staying in the equipment room, providing great convenience for users.

VLAN SPAN (VSPAN) considers data streams of some VLANs as data sources and mirrors them to a destination port. The configuration is similar to that of the port-based SPAN. VSPAN has the following features:

- A VLAN that is not a remote VLAN can be specified as the data source of VSPAN.

- Some VLANs that are not remote VLANs can be specified as the data sources of VSPAN.
- When a VLAN is configured as a data source, packets only in the Rx direction can be mirrored.

## 5.2 Applications

Application	Description
<u>Stream-based SPAN</u>	Data streams with certain characteristics need to be monitored, for example, data streams using a specified access control list (ACL) policy need to be monitored.
<u>One-to-Many RSPAN</u>	Multiple users need to monitor data of the same port.
<u>RSPAN Basic Applications</u>	Packets on the mirroring source device need to be mirrored to the destination device for monitoring.

### 5.2.1 Stream-based SPAN

#### Scenario

As shown in the following figure, the network analyzer can be configured to can monitor all data streams forwarded by Switch A to Switch B and specific data streams of Switch B (for example, data streams from PC1 and PC2).

Figure 5-2 SPAN Simple Application Topology

**Remarks** 0000.0000.0001 is the MAC address of PC1.  
0000.0000.0002 is the MAC address of PC2.

#### Deployment

- In the preceding figure, configure the SPAN function on Switch A connected to the network analyzer, set port Gi 0/1 connected to Switch B as the SPAN source port, and set port Gi 0/2 that is directly connected to the network analyzer as the SPAN destination port.
- Configure stream-based SPAN (only data streams of PC1 and PC2 are allowed) for the source port Gi 0/1 of SPAN.

### 5.2.2 One-to-Many RSPAN

#### Scenario

As shown in the following figure, one-to-many RSPAN can be implemented on a single device, that is, both PC 1 and PC 2 can be configured to monitor the transmitted and received traffic of the port connected to the server. Users can make proper configuration (for example, remote VLAN and port MAC loopback) to monitor data streams that pass through port Gi 4/1 on PC 1 and PC 2, thereby monitoring data streams of the server.

Figure 5-3 Application Topology of One-to-Many RSPAN

### Deployment

- Create a remote VLAN on Switch A.
- Configure Switch A as the source device of RSPAN and configure the port Gi 4/1 that is directly connected to the server as the RSPAN source port. Select a port that is in the Down state, Gi 4/2 in this example, as the RSPAN output port, add this port to the remote VLAN, and configure MAC loopback (run the **mac-loopback** command in interface configuration mode).
- Add ports that are directly connected to PC 1 and PC 2 to the remote VLAN.
- **i** Run the **mac-loopback remove-itag** command if removal of the inner VLAN tag in the input direction of the loopback port is needed.

### 5.2.3 RSPAN Basic Applications

#### Scenario

As shown in the following figure, the RSPAN function enables the network analyzer to monitor the STA connected to the source device Switch A from the destination device Switch C through the intermediate device Switch B. The devices can normally exchange data with each other.

Figure 5-4 Basic Application Topology of RSPAN

## Deployment

- Configure a remote VLAN on Switch A, Switch B, and Switch C.
- On Switch A, configure port Gi0/1 directly connected to the STA as the source port, configure port Gi0/2 connected to Switch B as the output port, and configure the switching function for the output port.
- On Switch B, configure port Gi0/1 connected to Switch A and port Gi0/2 connected to Switch C as common ports.
- On Switch C, configure port Gi0/1 connected to Switch B as a common source port, configure port Gi0/2 connected to the network analyzer as the RSPAN destination port, and configure the switching function for the RSPAN destination port.

## 5.3 Features

### Basic Concepts

#### ▾ SPAN Session

A SPAN session is data streams between the SPAN source port and the destination port, which can be used to monitor the packets of one or more ports in the input, output, or both directions. Switched ports, routed ports, and aggregate ports (APs) can be configured as source ports or destination ports of SPAN sessions. Normal operations on a switch are not affected after ports of the switch are added to a SPAN session.

Users can configure a SPAN session on a disabled port but the SPAN session is inactive. A SPAN session is in the active state only after the port on which the SPAN session is configured is enabled. In addition, a SPAN session does not take effect after a switch is powered on. It is active only after the destination port is in the operational state. Users can run the **show monitor [session session-num]** command to display the operation status of a SPAN session.

#### ▾ SPAN Data Streams

A SPAN session covers data streams in three directions:

- **Input data streams:** All packets received by a source port are copied to the destination port. Users can monitor input packets of one or more source ports in a SPAN session. Some input packets of a source port may be discarded for some reasons (for example, for the sake of port security). It does not affect the SPAN function and such packets are still mirrored to the destination port.
- **Output data streams:** All packets transmitted by a source port are copied to the destination port. Users can monitor output packets of one or more source ports in a SPAN session. Packets transmitted from other ports to a source port may be discarded for some reasons and such packets will not be transmitted to the destination port. The format of output packets of a source port may be changed for some reasons. For example, after routing, packets transmitted from the source port are changed in source

MAC addresses, destination MAC addresses, VLAN IDs, and TTLs, and their formats are also changed after copied to the destination port.

- Bidirectional data streams: Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

#### ▾ Source Port

A source port is called a monitored port. In a SPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single SPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not restricted.

A source port has the following features:

- A source port can be a switched port, routed port, or AP.
- A source port cannot be used as a destination port simultaneously.
- A source port and a destination port can belong to the same VLAN or different VLANs.

#### ▾ Destination Port

A SPAN session has one destination port (called a monitoring port) for receiving packets copied from a source port.

A destination port has the following features:

- A destination port can be a switched port, routed port, or AP.
- A destination port cannot be used as a source port simultaneously.

#### Overview

Feature	Description
<u>SPAN</u>	Configures mirroring of ports on the same device.
<u>RSPAN</u>	Configures mirroring of ports on different devices.

#### 5.3.1 SPAN

SPAN is used to monitor data streams on switches. It copies frames on one port to another switch port that is connected to a network analyzer or RMON analyzer so as to analyze the communication of the port.

#### Working Principle

When a port transmits or receive packets, SPAN, after checking that the port is configured as a SPAN source port, copies the packets transmitted and received by the port to the destination port.

#### ▾ Configuring a SPAN Source Port

Users need to specify a SPAN session ID and source port ID to configure a SPAN source port, and set the optional SPAN direction item to determine the direction of SPAN data streams or specify an ACL policy to mirror specific data streams.

#### ▾ Configuring a SPAN Destination Port

Users need to specify a SPAN session ID and destination port ID to configure a SPAN destination port, and set the optional switching function item to determine whether to enable the switching function and tag removal function on the SPAN destination port.

## Related Configuration

The SPAN function is disabled by default. It is enabled only after a session is created, and the SPAN source and destination ports are configured. A SPAN session can be created when a SPAN source port or destination port is configured.

### ✎ Configuring a SPAN Source Port

A SPAN session does not have a SPAN source port by default. Users can run the following command to configure a SPAN source port:

```
monitor session session-num source interface interface-id [both|rx|tx][acl name]
```

In the preceding command:

*session-num*: Indicates the SPAN session ID. The number of supported SPAN sessions varies with products.

*interface-id*: Indicates the SPAN source port to be configured.

**rx**: Indicates that only packets received by the source port are monitored after **rx** is configured.

**tx**: Indicates that only packets transmitted by the source port are monitored after **tx** is configured.

**both**: Indicates that packets transmitted and received by the source port are copied to the destination port for monitoring after **both** is configured, that is, **both** includes **rx** and **tx**. If none of **rx**, **tx**, and **both** is selected, **both** is enabled by default.

**acl**: Specifies an ACL policy. After this option is configured, packets allowed by the ACL policy on the source port are monitored. This function is disabled by default.

### ✎ Configuring a SPAN Destination Port

A SPAN session does not have a SPAN destination port by default. Users can run the following command to configure a SPAN destination port:

```
monitor session session-num destination interface interface-id [switch]
```

In the preceding command:

**switch**: Indicates that the SPAN destination port only receives packets mirrored from the SPAN source port and discards other packets if this option is disabled, and receives both packets mirrored from the SPAN source port and packets from non-source ports if this option is enabled, that is, the communication between this destination port and other devices is not affected.

When the SPAN destination port is configured, the relevant function is disabled by default if **switch** is not configured.

### ✎ Configuring Stream-based SPAN

This function is disabled by default. Users can run the **monitor session** *session-num* **source interface** *interface-id* **rx** **acl** *acl-name* command to configure stream-based SPAN.

Pay attention to the following points when using SPAN:

The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.

SPAN is unavailable if a source port or destination port is disabled.

If a VLAN (or VLAN list) is used as a SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the VLAN (or VLAN list).

Not all products support all options of the preceding commands because of product differences.

### 5.3.2 RSPAN

RSPAN is capable of monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port.

#### Working Principle

A remote VLAN is created for the source device, intermediate device, and destination device, all ports involved in an RSPAN session need to be added to the remote VLAN. Mirrored packets are broadcasted in the remote VLAN so that they are transmitted from the source port of the source switch to the destination port of the destination switch.

#### ✚ Configuring a Remote VLAN

Packets from an RSPAN source port are broadcasted in a remote VLAN so as to be copied from the local switch to the remote switch. The RSPAN source port, output port, reflection port, transparent transmission ports of the intermediate device (packet input port and output port of the intermediate device), destination port and input port of the destination port must be added to the remote VLAN. The RSPAN function requires configuring a VLAN as a remote VLAN in VLAN mode. The remote VLAN configuration in the loopback topology will become invalid after the VLAN interface is created.

#### ✚ Configuring an RSPAN Session

The configuration of the RSPAN source port and destination port are similar to that of the SPAN source port and destination port, but the mirroring session ID specified during configuration must be the ID of an RSPAN session.

#### ✚ Configuring an RSPAN Source Port

The configuration of an RSPAN source port is the same as that of a SPAN source port, but the specified mirroring session ID must be the ID of an RSPAN session.

#### ✚ Configuring an RSPAN Output Port

The output port is located on the source device and must be added to a remote VLAN. Mirrored packets of a source port are broadcasted in this remote VLAN. The source device transmits packets to the intermediate switch or destination switch through the output port.

#### ✚ Configuring an RSPAN Destination Port

When an RSPAN destination port is configured, an RSPAN session ID, remote VLAN, and port name must be specified so that packets from the source port are copied to the destination port through the remote VLAN.

#### ✚ Configuring Stream-based RSPAN

RSPAN is an extension to SPAN and also supports stream-based mirroring. The configuration is the same as that of stream-based SPAN. Stream-based RSPAN does not affect normal communication.

Users can configure an ACL in the input direction of a source port on an RSPAN source device. Standard ACLs, extended ACLs, MAC ACLs, and user-defined ACLs are supported.

Users can configure a port ACL in the input direction of a source port on an RSPAN source device, and configure a port ACL in the output direction of the destination port on the RSPAN destination device. Users can also configure an ACL in the output direction of a remote VLAN on an RSPAN source switch and configure an ACL in the input direction of the remote VLAN on the RSPAN destination switch.

## ▾ Configuring One-to-Many RSPAN

If data streams of one source port need to be mirrored to multiple destination ports, users can configure an RSPAN session, configure the source port of the RSPAN session as a one-to-many mirroring source port and select another Ethernet port as the forwarding port (output port on the source device). In addition, the MAC loopback function needs to be configured on the RSPAN forwarding port in interface configuration mode, the expected RSPAN output port and RSPAN forwarding port need to be added to the remote VLAN. Then, mirrored packets are looped back on the RSPAN forwarding port and then broadcasted in the remote VLAN, thereby implementing one-to-many RSPAN.

### Related Configuration

The RSPAN function is disabled by default. It is enabled only after an RSPAN session is created, and a remote VLAN, RSPAN source port, and RSPAN destination port are configured.

## ▾ Configuring a Remote VLAN

No remote VLAN is specified for RSPAN by default. Users can run the **remote-span** command in VLAN mode to configure a VLAN as a remote VLAN. One remote VLAN corresponds to one RSPAN session.

## ▾ Configuring an RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num remote-source** command in global configuration mode to configure a device as the remote source device of a specified RSPAN session.

## ▾ Configuring an RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num remote-destination** command in global configuration mode to configure a device as the remote destination device of a specified RSPAN session.

## ▾ Configuring an RSPAN Source Port

A source port of an RSPAN session is configured on the source device. The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified. This function is disabled by default.

## ▾ Configuring an Output Port on the RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num destination remote-vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure an output port on the RSPAN source device. If the option **switch** is configured, the output port can participate in normal data packet switching. It is not configured by default. The output port must be added to a remote VLAN.

## ▾ Configuring a Destination Port on the RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num destination remote-vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure a destination port on the RSPAN destination device. If the option **switch** is configured, the destination port can participate in normal data packet switching. It is not configured by default. The destination port must be added to a remote VLAN.

Pay attention to the following points when using RSPAN:

A remote VLAN must be configured on each device, their VLAN IDs must be consistent, and all ports that participate in a session must be added to the VLAN.

It is not recommended that common ports be added to a remote VLAN.

 Do not configure a port that is connected to an intermediate switch or destination switch as an RSPAN source port. Otherwise, traffic on the network may be in chaos.

## 5.4 Configuration

Configuration	Description and Command	
<u>Configuring</u> <u>SPAN Basic</u> <u>Functions</u>	 (Mandatory) It is used to create SPAN.	
	<b>monitor session</b> <i>session-num</i> <b>source interface</b> <i>interface-id</i> [ <b>both</b>   <b>rx</b>   <b>tx</b> ]	Configures a SPAN source port.
	<b>monitor session</b> <i>session-num</i> <b>destination interface</b> <i>interface-id</i> [ <b>switch</b> ]	Configures a SPAN destination port.
	<b>monitor session</b> <i>session-num</i> <b>source interface</b> <i>interface-id</i> <b>rxacl</b> <i>acl-name</i>	Configures stream-based SPAN.
	<b>monitor session</b> <i>session-num</i> <b>source vlan</b> <i>vlan-id</i> [ <b>rx</b> ]	Specifies a VLAN as the data source of SPAN.
	<b>monitor session</b> <i>session-num</i> <b>filter vlan</b> <i>vlan-id-list</i> [ <b>rx</b>   <b>tx</b>   <b>both</b> ]	Specifies some VLANs as the data sources of SPAN.
<u>Configuring</u> <u>RSPAN Basic</u> <u>Functions</u>	 (Mandatory) It is used to create RSPAN.	
	<b>monitor session</b> <i>session-num</i> <b>remote-source</b>	Configures an RSPAN session ID and specifies a source device.
	<b>monitor session</b> <i>session-num</i> <b>remote-destination</b>	Configures an RSPAN session ID and specifies a destination device.
	<b>remote-span</b>	Configures a remote VLAN.
	<b>monitor session</b> <i>session-num</i> <b>source interface</b> <i>interface-id</i> [ <b>both</b>   <b>rx</b>   <b>tx</b> ]	Configures an RSPAN source port.
	<b>monitor session</b> <i>session-num</i> <b>destination remote vlan</b> <i>remote-vlan-id</i> <b>interface</b> <i>interface-id</i> [ <b>switch</b> ]	Configures an output port on the RSPAN source device or a destination port on the RSPAN destination device.

### 5.4.1 Configuring SPAN Basic Functions

#### Configuration Effect

- Configure a source and destination ports for a SPAN session.
- Configure a destination port to monitor any packets transmitted and received by a source port.

#### Notes

- If the switch function is disabled on a SPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.

#### Configuration Steps

### ✚ Configuring a SPAN Session

- Global configuration mode. Mandatory.
- You can configure a SPAN session when configuring a SPAN source port or destination port, or when configuring a specified VLAN or some VLANs as a data source or data sources of SPAN.

### ✚ Configuring a SPAN Source Port

- Global configuration mode. Mandatory.
- You can select the SPAN direction when configuring a SPAN source port. The **both** direction is configured by default, that is, both transmitted and received packets are monitored.

### ✚ Configuring a SPAN Destination Port

Global configuration mode. Mandatory.

A SPAN session is active only when a SPAN source port is configured (or a VLAN is specified as the data source of SPAN) and a SPAN destination port is configured.

### Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. Alternatively, conduct packet capture analysis on the SPAN destination port and check whether the SPAN function takes effect according to the captured packets.

### Related Commands

#### ✚ Configuring a SPAN Source Port

<b>Command</b>	<b>monitor session</b> <i>session-num</i> <b>source interface</b> <i>interface-id</i> [ <b>both</b>   <b>rx</b>   <b>tx</b> ]
<b>Parameter Description</b>	<p><i>session-num</i>: Indicates the ID of a SPAN session.</p> <p><i>interface-id</i>: Indicates the interface ID.</p> <p><b>both</b>: Indicates that packets in the input and output directions are monitored. It is the default value.</p> <p><b>rx</b>: Indicates that packets in the input direction are monitored.</p> <p><b>tx</b>: Indicates that packets in the output direction are monitored.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ✚ Configuring a SPAN Destination Port

<b>Command</b>	<b>monitor session</b> <i>session-num</i> <b>destination interface</b> <i>interface-id</i> [ <b>switch</b> ]
<b>Parameter Description</b>	<p><i>session-num</i>: Indicates the ID of a SPAN session.</p> <p><i>interface-id</i>: Indicates the interface ID.</p> <p><b>switch</b>: Indicates that the switching function is enabled on the SPAN destination port. It is disabled by default.</p>
<b>Command</b>	Global configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	N/A

### ↘ Configuring Stream-based SPAN

<b>Command</b>	<b>monitor session</b> <i>session-num</i> <b>source interface</b> <i>interface-id</i> <b>rx acl</b> <i>acl-name</i>
<b>Parameter Description</b>	<p><i>session-num</i>: Indicates the ID of a SPAN session.</p> <p><i>interface-id</i>: Indicates the interface ID.</p> <p><i>acl-name</i>: Indicates an ACL name.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### ↘ Specifying a VLAN as the Data Source of SPAN

<b>Command</b>	<b>monitor session</b> <i>session-num</i> <b>source vlan</b> <i>vlan-id</i> [ <b>rx</b> ]
<b>Parameter Description</b>	<p><i>session-num</i>: Indicates the ID of a SPAN session.</p> <p><i>vlan-id</i>: Indicates a specified VLAN ID.</p> <p><b>rx</b>: Indicates that packets in the input direction are monitored.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### ↘ Specifying Some VLANs as the Data Sources of SPAN

<b>Command</b>	<b>monitor session</b> <i>session-num</i> <b>filter vlan</b> <i>vlan-id-list</i> [ <b>rx</b>   <b>tx</b>   <b>both</b> ]
<b>Parameter Description</b>	<p><i>session-num</i>: Indicates the ID of a SPAN session.</p> <p><i>vlan-id-list</i>: Indicates some specified VLAN IDs.</p> <p><b>rx</b>: Indicates that packets in the input direction are monitored.</p> <p><b>tx</b>: Indicates that packets in the output direction are monitored.</p> <p><b>both</b>: Indicates that packets in both input and output directions are monitored. (Default settings)</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Configuration Example

↘ The following uses SPAN as an example.

<b>Scenario</b> <b>Figure 5-5</b>	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>As shown in Figure 5-5, add ports Gi 0/1 and Gi 0/2 of Device A to VLAN 1.</li> <li>Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24.</li> <li>Set IP addresses of PC 1 and PC 2 to 10.10.10.1/24 and 10.10.10.2/24 respectively.</li> <li>Configure SPAN for Device A and configure ports Gi 0/1 and Gi 0/2 as the source port and destination port of SPAN respectively.</li> </ul>
<b>A</b>	<pre> FS# configure FS(config)# vlan 1 FS(config-vlan)# exit FS(config)# interface vlan 1 FS(config-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0 FS(config-if-VLAN 1)# exit FS(config)# monitor session 1 source interface gigabitEthernet 0/1 FS(config)# monitor session 1 destination interface gigabitEthernet 0/2 </pre>
<b>Verification</b>	<p>Run the <b>show monitor</b> command to check whether SPAN is configured correctly. After successful configuration, PC 1 sends ping packets to SVI 1 and PC 2 conducts monitoring by using the packet capture tool.</p>
<b>A</b>	<pre> FS# show monitor sess-num: 1 span-type: LOCAL_SPAN src-intf: GigabitEthernet0/1      frame-type Both dest-intf: GigabitEthernet 0/2 </pre>

### Common Errors

- The session ID specified during configuration of the SPAN source port is inconsistent with that specified during configuration of the SPAN destination port.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.

## 5.4.2 Configuring RSPAN Basic Functions

### Configuration Effect

- Configure a source port and destination port on the source device of an RSPAN session and configure the destination port on the destination device.
- Configure the destination port on the RSPAN destination device to monitor any packets that are transmitted or received by the source port.

### Notes

- If the switch function is disabled on an RSPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.
- All ports involved in RSPAN must be added to a remote VLAN.
- A remote VLAN must be created on an intermediate device and transparent transmission ports must be added to the remote VLAN.

### Configuration Steps

#### ▾ Configuring an RSPAN Session

- Global configuration mode. Mandatory.
- The same session ID needs to be configured on the RSPAN source device and RSPAN destination device.

#### ▾ Configuring an RSPAN Source Device

- Global configuration mode. Mandatory.
- It is used to specify a device to be monitored by RSPAN.

#### ▾ Configuring an RSPAN Destination Device

- Global configuration mode. Mandatory.
- It is used to specify the destination device for outputting RSPAN packets.

#### ▾ Configuring an RSPAN Source Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, RSPAN monitoring can be conducted on packets of the RSPAN source port. You can specify RSPAN to monitor remote VLAN packets in the input direction, output direction, or both directions of the RSPAN source port.

#### ▾ Configuring an RSPAN Output Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, mirrored packets received by the ports added to the remote VLAN can be transmitted to the RSPAN destination device through the output port.

#### ▾ Configuring an RSPAN Destination Port

- Global configuration mode. Mandatory.

- Complete the configuration on the RSPAN destination device. After configuration, the RSPAN destination device forwards mirrored packets received by the ports added to the remote VLAN to the monitoring device through the destination port.

#### Verification

- Run the **show monitor** command or the **show running** command to check whether RSPAN is successfully configured on each device, or conduct packet capture on the destination mirroring port on the RSPAN destination device to check whether packets mirrored from the source port of the RSPAN source device are captured.

▾ **Configuring a Destination Port on the RSPAN Destination Device**

<b>Command</b>	<b>monitor session <i>session-num</i> destination remote vlan <i>remote-vlan</i> interface <i>interface-id</i> [ switch ]</b>
<b>Parameter Description</b>	<i>session-num</i> : Indicates the ID of an RSPAN session. <i>remote-vlan</i> : Indicates a remote VLAN. <i>interface-id</i> : Indicates the interface ID. <b>switch</b> : Indicates whether the port participates in packet switching.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

**Configuration Example**

▾ **Configuring One-to-Many RSPAN**

<p><b>Scenario</b> Figure 5-6</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● As shown in the preceding figure, configure a remote VLAN on Switch A, Switch B, and Switch C.</li> <li>● Configure the source port, output port and loopback port on Switch A.</li> <li>● Configure the destination port on Switch B and Switch C.</li> </ul>
<p><b>A</b></p>	<pre>FS# configure</pre>

	<pre> FS(config)# vlan 7 FS(config-vlan)# remote-span FS(config-vlan)# exit FS(config)# monitor session 1 remote-source FS(config)# monitor session 1 source interface fa 0/1 both FS(config)# monitor session 1 destination remote vlan 7 interface fa0/2 switch FS(config)# interface fa0/2 FS(config-if)# mac-loopback FS(config-if)# switchport access vlan 7 FS(config-if)# exit FS(config)# interface range fa0/3-4 FS(config-if-range)# switchport mode trunk </pre>
<b>B, C</b>	<pre> FS(config)# vlan 7 FS(config-vlan)# remote-span FS(config-vlan)# exit FS(config)# monitor session 1 remote-destination FS(config)# monitor session 1 destination remote vlan 7 interface fa 0/2 FS(config)# interface fa0/1 FS(config-if)# switchport mode trunk </pre>
<b>Verification</b>	Run the <b>show monitor</b> command or the <b>show running</b> command on Switch A, Switch B, and Switch C to check whether RSPAN is configured successfully.
<b>A</b>	<pre> FS# show monitor sess-num: 1 span-type: SOURCE_SPAN src-intf: FastEthernet 0/1      frame-type Both dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on </pre>
<b>B</b>	<pre> FS# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: </pre>

	FastEthernet 0/2 Remote vlan 7 mtp_switch on
<b>C</b>	FS# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on

### Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.
- Multiple output ports need to be configured to implement one-to-many RSPAN.

## 5.5 Monitoring

### Displaying

Description	Command
Displays all mirroring sessions existing in the system.	<b>show monitor</b>
Displays a specified mirroring session.	<b>show monitor session <i>session-id</i></b>

### Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	<b>debug span</b>

## 6 Configuring ERSPAN

### 6.1 Overview

Encapsulated Remote Switched Port Analyzer (ERSPAN) is an extension to Remote Switched Port Analyzer (RSPAN). SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

An ERSPAN encapsulates all SPAN packets into IP packets through a generic routing encapsulation (GRE) tunnel, and routes them to the destination port of an RSPAN device. The following figure shows the topology of a typical application:

Figure 6-1 Topology of a Typical ERSPAN GRE Tunnel Application

There are two kinds of roles played by the devices in the figure:

- **Source switch:** A source switch refers to the switch where the ERSPAN source port resides. It copies the packets on the source port, outputs the copies from the output port, encapsulates them into IP packets, and forwards the IP packets to the destination switch.
- **Destination switch:** A destination switch refers to the switch where the ERSPAN destination port resides. It puts the received SPAN packets through the SPAN destination port, decapsulates them into GRE packets, and then forwards the GRE packets to the monitoring device.

To implement ERSPAN, the GRE-encapsulate IP packets must be able to be normally routed to the destination SPAN device.

## 6.2 Applications

Application	Description
<a href="#">Basic ERSPAN Applications</a>	Packets on the SPAN source device need to be mirrored to the destination device for monitoring.

### 6.3 Basic ERSPAN Applications

#### Scenario

As shown in the following figure, ERSPAN enables the network analyzer to monitor the users connected to the source device Switch A. The devices can normally exchange data with each other.

Figure 6-2 Topology of Basic ERSPAN Applications

### Deployment

- On Switch A, configure the port directly connected to users (Gi0/1) as a source port, and configure the port connected to Switch B (Gi0/2) as an output port.
- On Switch B, the ports connected to Switch A and Switch C (Gi0/1 and Gi0/2) are respectively member interfaces of switch virtual interface (SVI) interfaces of two network segments, ensuring interworking between the two IP network segments.

## 6.4 Features

### Basic Concepts

#### ↳ ERSPAN Session

SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, ERSPAN mirroring allows SPAN packets to be transmitted between routing networks. An ERSPAN encapsulates all SPAN packets into IP packets through a GRE tunnel, and routes them to the destination port of an RSPAN device. An ERSPAN can monitor input, output, and bidirectional packets of one or more ports. Ports such as a switched port, routed port and aggregate port (AP) can be configured as a source port for an ERSPAN session. The switch is not affected after the port is added to an ERSPAN session.

#### ↳ Source Port

A source port is also called a monitored port. In an ERSPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single ERSPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not limited. A source port has the following features:

- A source port can be a switched port, routed port, or an AP.
- It supports mirroring of multiple source ports on the source device to the designated output ports.
- The source port and output port cannot be on the same port; when the SPAN source port is a Layer-3 interface, both Layer-2 and Layer-3 packets are monitored.
- When multiple ports are bidirectionally monitored, a packet is input from a port and output from the other. Such monitoring is considered correct if only one packet is monitored.

- When the status of enabled Spanning Tree Protocol (STP) port is in block state, the input and output packets on the port can be monitored;
- Source port and destination port can belong to the same VLAN or different VLANs.

## Overview

Feature	Description
ERSPAN	Configures SPAN on different Internet ports.

### 6.4.1 ERSPAN

Encapsulated ERSPAN is an extension of RSPAN. SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

#### Working Principle

All the mirrored packets are encapsulated into IP packets through a GRE tunnel, and routed to the destination port of an RSPAN device.

#### ✚ Configuring an ERSPAN Session

Configure ERSPAN of the switch, and distinguish between attributes of ERSPAN switch of the device. You need to designate an ERSPAN session ID, and enter the ERSPAN configuration mode after configuration succeeds.

#### ✚ Configuring a Source Port

After entering the ERSPAN configuration mode, you need to name the source port to configure the SPAN source port, and determine the direction of SPAN data streams according to optional configurations of SPAN direction.

#### ✚ Enabling an ERSPAN Session

By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

#### ✚ Encapsulating the Origin IP Address

Encapsulating an origin IP address aims to configure the origin IP address of an encapsulated GRE packet.

#### ✚ Encapsulating the Destination IP Address

Encapsulating a destination IP address aims to configure the destination IP address of an encapsulated GRE packet and ensure normal routing of SPAN packets on the network.

#### ✚ Encapsulating IP TTL/DSCP

Encapsulate Time to Live (TTL) and Differentiated Services Code Point (DSCP) values of IP packets.

#### ✚ Configuring Capture Mode

Configure the capture mode (whether to mirror the entire packet or the header bytes of the original packet).

#### ✚ Configuring Sampling Frequency

Configure the sampling frequency (the number of packets for one mirroring operation) for mirroring on the source port.

#### ✚ `vrf vrf-name`

It indicates the name of virtual routing. Different virtual routing values might obtain different egresses for the same destination IP.

### Related Configuration

By default, an SPAN is disabled. It is enabled only after a session is created, and source SPAN port, origin IP and destination IP addresses are configured.

#### ✚ Configuring an ERSPAN Session

```
FS(config)# monitor session session_num erspan-source
```

Wherein,

*session-num*: Indicates that the number of SPAN sessions supported by SPAN session IDs varies with products.

#### ✚ Configuring a Source Port

```
FS(config-mon-erspan-src)# source interface {single-interface | all} { [ rx | tx | both ] }
```

Wherein,

*single\_interface*: Indicates the SPAN source port to be configured.

**all**: Indicates that the to-be-configured SPAN source port is global interfaces that support mirroring.

**rx**: Indicates that only the packets received by the source port are monitored after **rx** is configured.

**tx**: Indicates that only the packets sent from the source port are monitored after **tx** is configured.

**both**: Indicates that after **both** is configured, the packets sent and received by the source port are transmitted to the destination port to be monitored; that is to say, **both** includes **rx** and **tx**. If none of **rx**, **tx**, or **both** is configured, **both** is enabled by default.

#### ✚ Configuring Stream-based SPAN

The function is disabled by default. Run the FS(config-mon-erspan-src)# **source interface** *interface-id* **rx acl** *acl-name* { *sample* } command to configure stream-based SPANs and the sampling frequency (optional).

#### ✚ Enabling an ERSAN Session

```
FS (config-mon-erspan-src)# shutdown
```

This command is used to disable ERSPAN mirroring. (By default) Run the **no shutdown** command to enable ERSPAN mirroring.

#### ✚ Encapsulating the Destination IP Address

```
FS(config-mon-erspan-src)# destination ip address ip-address
```

Wherein,

*ip-address*: Encapsulates the destination IP address.

#### ✚ Encapsulating the Origin IP Address

```
FS(config-mon-erspan-src)# origin ip address ip-address
```

Wherein,

*ip-address*: Encapsulates the origin IP address.

#### ✚ Encapsulating IPTTL

```
FS(config-mon-erspan-src)# ip ttl ttl_value
```

Wherein,

*ttl\_value*: Configures the TTL value of an encapsulated IP address. The TTL value ranges from 0 to 255, and the default value is 64.

### ✚ Encapsulating IP DSCP

FS(config-mon-erspan-src)# **ip dscp** *dscp\_value*

Wherein,

*dscp\_value*: Configures the DSCP value of an encapsulated IP address. The DSCP value ranges from 0 to 63, and the default value is 0.

The function takes effect only after trusting DSCP is configured on the SPAN source port.

### ✚ Configuring Capture Mode

FS(config-mon-erspan-src)# **capture-mode** [ **all** | **truncate** ]

**all**: default value, which indicates that the entire original packet is mirrored.

**truncate**: Indicates that the header byte of the original packet is mirrored. A specific number of header bytes to be mirrored is determined by the product chip.

### ✚ Configuring Sampling Frequency

FS(config-mon-erspan-src)# **sampling-rate** *rate*

*rate*: Indicates the sampling frequency value, ranging from 1 to 1000000. For example, if the sampling frequency is 100, one packet is sampled from 100 packets, that is, the sampling ratio is 100:1. The default sampling frequency is 1:1, that is, each packet is sampled.

This function is valid only when the sampling frequency is configured on the SPAN source port.

### ✚ Encapsulating vrf *vrf-name*

FS(config-mon-erspan-src)# **vrf** *vrf-name*

Wherein,

*vrf-name*: Indicates the name of VPN Routing & Forwarding Instance (VRF).

 Pay attention to the following issues during use:

- Confirm the Layer-3 routing connectivity from source switch to destination switch.
- ERSPAN is unavailable if a source port is disabled.
- If a source port or destination port is added to an AP, the source port or destination port egresses an ERSPAN session.
- As a result of product differences, not all products support all options of the above-mentioned commands.

## 6.5 Configuration

Configuration	Description and Command	
<a href="#">Configuring Basic ERSPAN Functions</a>	 (Mandatory) It is used to create ERSPAN mirroring.	
	<b>monitor session</b> <i>erspan_source_session_number</i> <b>erspan-source</b>	Configures an ERSPAN session ID, and enters the configuration mode of the source ERSPAN device.
	<b>source interface</b> { <i>single-interface</i>   <b>all</b> } { <b>rx</b>   <b>tx</b>   <b>both</b> }	Associates the source ERSPAN port, and selects an SPAN direction.
	<b>source interface</b> { <i>single-interface</i>   <b>all</b> } <b>rx acl</b> <i>acl-name</i>	Configures the stream-based SPAN source for ERSPAN and

[ sample ]	enables sampling.
shutdown	Disables ERSPAN mirroring.
destination ip address <i>ip_address</i>	Configures the destination IP address for an ERSPAN stream. The address must be the interface address of the destination device.
original ip address <i>ip_address</i>	Configures the encapsulated origin IP address for ERSPAN.
ip ttl <i>ttl_value</i>	(Optional) Configures the TTL value of an encapsulated IP address for ERSPAN.
ip dscp <i>dscp_value</i>	(Optional) Configures the DSCP field value of an encapsulated IP address for ERSPAN.
capture-mode [ all   truncate ]	(Optional) Configures the capture mode for mirroring the original packet.
sampling-rate <i>rate</i>	(Optional) Configures the sampling frequency for mirroring.
vrf <i>vrf_name</i>	(Optional) Configures the VRF name.

### 6.5.1 Configuring Basic ERSPAN Functions

#### Configuration Effect

- RSPAN enables a network analyzer to monitor users.
- Devices can normally exchange data with each other.

#### Notes

- If a source port is added to an AP, the source port egresses an ERSPAN session.
- The Layer-3 routing connectivity from source switch to destination switch must be ensured.

#### Configuration Steps

##### ● ERSPAN Session

- Global configuration mode. Mandatory.
- The session ID configured with local SPAN or RSPAN cannot be used for an ERSPAN session. Enter the ERSPAN mode after configuration.

##### ↘ Source Port

- ERSPAN configuration mode. Mandatory.
- An SPAN direction can be selected during configuration of the SPAN source port. The direction is **both** by default; that is, both reception and transmission of packets are monitored.

##### ↘ Enabling an ERSPAN Session

- ERSPAN configuration mode. Mandatory.
- By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

##### ↘ Encapsulating the Origin IP Address

- ERSPAN configuration mode. Mandatory.

- It is used to encapsulate origin IP addresses of SPAN packets.

#### ↘ Encapsulating the Destination IP Address

- ERSPAN configuration mode. Mandatory.
- It is used to encapsulate destination IP addresses of SPAN packets.

#### ↘ Encapsulating IP TTL/DSCP

- ERSPAN configuration mode. Optional.
- It is used to encapsulate DSCP values of SPAN IP packets.

#### ↘ Configuring Capture Mode

- ERSPAN configuration mode. Optional.
- It is used to configure the capture mode for mirroring the original packet.

#### ↘ Configuring Sampling Frequency

- ERSPAN configuration mode. Optional.
- It is used to configure the sampling frequency for mirroring.

#### ↘ vrf vrf-name

- Global configuration mode. Optional.
- It indicates the name of VRF. VRF must exist.

#### Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. You can also conduct packet capture analysis on the SPAN destination port and check whether SPAN takes effect according to the captured packets.

#### Related Commands

##### ↘ Configuring an ERSPAN Session

<b>Command</b>	<b>monitor session <i>session_number</i> erspan-source</b>
<b>Parameter Description</b>	<i>session-num</i> : Indicates the SPAN session ID.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

##### ↘ Configuring a Source Port

<b>Command</b>	<b>source interface { <i>single-interface</i>   all } [{ rx   tx   both }]</b>
<b>Parameter Description</b>	<i>single_interface</i> : Indicates the SPAN session ID. <b>all</b> : Indicates global interfaces that support mirroring. <b>both</b> : Monitors both input and output packets by default. <b>rx</b> : Monitors only input packets. <b>tx</b> : Monitors only output packets.

<b>Command Mode</b>	ERSPAN session mode
<b>Usage Guide</b>	N/A

### ↘ Configuring Stream-based SPAN

<b>Command</b>	<b>source interface { <i>single-interface</i>   all } rx acl <i>acl-name</i> sample</b>
<b>Parameter Description</b>	<i>single-interface</i> : Indicates the interface name. <b>all</b> : Indicates global interfaces that support mirroring. <i>acl-name</i> : Indicates the ACL name. <b>sample</b> : Indicates whether the sampling is enabled.
<b>Command Mode</b>	ERSPAN session mode
<b>Usage Guide</b>	N/A

### ↘ Enabling an ERSAN Session

<b>Command</b>	<b>shutdown</b>
<b>Parameter Description</b>	
<b>Command Mode</b>	ERSPAN session mode
<b>Usage Guide</b>	N/A

### ↘ Encapsulating the Origin IP Address

<b>Command</b>	<b>original ip address <i>ip_address</i></b>
<b>Parameter Description</b>	<i>ip_address</i> : Indicates the origin IP address to be encapsulated.
<b>Command Mode</b>	ERSPAN session mode
<b>Usage Guide</b>	

### ↘ Encapsulates the Destination IP Address

<b>Command</b>	<b>destination ip address <i>ip_address</i></b>
<b>Parameter Description</b>	<i>ip_address</i> : Indicates the destination IP address to be encapsulated.
<b>Command Mode</b>	ERSPAN session mode

### ↘ Configuring Capture Mode

<b>Command</b>	<b>capture-mode [ all   truncate ]</b>
<b>Parameter Description</b>	<b>all</b> : Indicates that the entire original packet is mirrored. <b>truncate</b> : Indicates that the header byte of the original packet is mirrored. A specific number of header bytes to be mirrored is determined by the product chip.
<b>Command Mode</b>	ERSPAN session mode

Usage Guide	N/A
-------------	-----

### ↘ Configuring Sampling Frequency

Command	<b>sampling-rate</b> <i>rate</i>
Parameter Description	<i>rate</i> : Indicates the required sampling frequency.
Command Mode	ERSPAN session mode

### ↘ Encapsulating IPTTL

Command	<b>ip ttl</b> <i>tll_value</i>
Parameter Description	<i>tll_value</i> : Configures the TTL value of an encapsulated IP address for ERSPAN. The value ranges from 1 to 255.
Command Mode	ERSPAN session mode
Usage Guide	-

### ↘ Encapsulating DSCP

Command	<b>ip dscp</b> <i>dscp_value</i>
Parameter Description	<i>dscp_value</i> : Configures the DSCP field value of an encapsulated IP address for ERSPAN. The value ranges from 0 to 64.
Command Mode	ERSPAN session mode
Usage Guide	-

### ↘ Configuring VRF *vrf-name*

Command	<b>vrf</b> <i>vrf_name</i>
Parameter Description	<i>vrf_name</i> : Indicates the VRF name.
Command Mode	ERSPAN session mode
Usage Guide	-

### Configuration Example

↘ The following uses a SPAN as an example.

<p><b>Scenario</b> <b>Figure 6-3</b></p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>As shown in Figure 6-3, on Switch A, create ERSPAN Session 1 and configure it as the source device, and configure Gi 0/1 as the source port.</li> </ul>
	<pre>SwitchA(config)#monitor session 1 erspan-source SwitchA(config-mon-erspan-src)#source interface gigabitEthernet 0/1 both SwitchA(config-mon-erspan-src)#origin ip address 10.1.1.2 SwitchA(config-mon-erspan-src)#destination ip address 12.1.1.2 SwitchA(config-mon-erspan-src)#vrf vrf-name</pre>
<p><b>Verification</b></p>	<p>Step 1: Check the configuration of the device.</p>
	<pre>SwitchA#show running-config ! monitor session 1 erspan-src   source interface GigabitEthernet 0/1 both   origin ip address 10.1.1.2   destination ip address 12.1.1.2 vrf vrf-name</pre>
	<p>Step 2: Check the ERSPAN information of the device.</p> <pre>SwitchA#show monitor sess-num: 1 //ERSPAN Session</pre>

```

span-type: ERSPAN_SOURCE //ERSPAN source device
src-intf: //ERSPAN source port information
GigabitEthernet0/1 frame-type Both TXstatus:Inactive RXstatus:Inactive
dest-intf: //ERSPAN output port information
GigabitEthernet 0/2
oFSin ip address 10.1.1.2
destination ip address 12.1.1.2
destination capture mode all
SwitchA#show monitor
sess-num: 1
span-type: ERSPAN_SOURCE
src-intf:
GigabitEthernet0/1 frame-type Both TXstatus:Inactive RXstatus:Inactive
dest-intf:
GigabitEthernet0/2
oFSin ip address 10.1.1.2
destination ip address 12.1.1.2
destination capture mode all
ip ttl 64
ip dscp 0
sample rate 0
vrf vrf-name
    
```

**Common Errors**

- The session ID used to configure ERSPAN mirroring is configured with RSPAN or LOCAL SPAN.
- Layer-3 routing interworking between source switch and destination switch fails.

**6.6 Monitoring**

**Displaying**

Description	Command
Displays all SPAN sessions in the system.	<b>show monitor</b>
Displays specific SPAN sessions.	<b>show monitor session <i>session-id</i></b>

**Debugging**

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	<b>debug span</b>

## 7 Configuring sFlow

### 7.1 Overview

sFlow is a network monitoring technology jointly developed by InMon, HP, and Foundry Networks in 2001. This technology has been standardized. It can provide complete traffic flows of Layer 2 to Layer 4, and it is applicable to traffic analysis in the extra-large network. This technology helps users analyze the performance, trend, and existence of network traffic flows in a detailed manner in real time.

sFlow has the following advantages:

- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

#### Protocol Specification

- sFlow Version 5
- RFC 1014

### 7.2 Applications

Typical Application	Scenario
<u>Monitoring the LAN Traffic</u>	Regard the device as an sFlow Agent, performs sampling of interface traffic in the LAN, and send the sFlow datagrams to an sFlow Collector for traffic analysis, thereby achieving the purpose of network monitoring.

#### 7.2.1 Monitoring the LAN Traffic

##### Application Scenario

As shown in Figure 7-1, start switch A that serves as an sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling data into sFlow datagrams at regular intervals or when the buffer is full, and send the sFlow data to the sFlow Collector for traffic analysis.

Figure 7-1

##### Function Deployment

- Configure the addresses of sFlow Agent and sFlow Collector on switch A.

- Enable flow sampling and counter sampling on port Te 0/1 of switch A.
- **i** Lots of server software supports sFlow. You can obtain software supporting sFlow at <http://www.sflow.oFS/products/collectors.php>. The software sflowtrend is free of charge.

### 7.3 Features

#### Basic Concepts

##### ↳ sFlow Agent

sFlow Agent is embedded in a network device. Generally, one network device can serve as an sFlow Agent. sFlow Agent can perform flow sampling and counter sampling, encapsulate sampled data into sFlow datagrams, and send the sFlow datagrams to the sFlow Collector.

sFlow datagrams are encapsulated in UDP. Figure 7-2 shows the sFlow datagram format.

Figure 7-2 sFlow Datagram Format

One sFlow datagram may contain one or multiple flow samples and counter samples.

Figure 7-3 sFlow Header

## sFlow Geader Description:

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, FS supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub-agent ID
Datagram sequence number	Serial number of the sFlow datagram
Switch uptime	Duration from the startup time of the switch to the current time
n samples in datagram	The number of samples in the an sFlow datagram. One sFlow datagram may contain one or multiple flow samples and counter samples.

### ↘ sFlow Collector

sFlow Collector receives and analyzes the sFlow datagram sent from the sFlow Agent. sFlow Collector may be a PC or server. A PC or server installed with the application software for sFlow datagram analysis can be regarded as an sFlow Collector.

### ↘ Flow Sampling

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet.

Figure 7-4 Flow Sample Header

1	8	32
int data format sample data (20 bit enterprise & 12 bit format) (standard enterprise 0, formats 1)		
int sample length byte		
int sample sequence number		
int source id type (0=ifIndex  1=smonVlanDataSource  2=entPhysicalEntry)	int source id index value	
int sampling rate		
int sample pool (total number of packets that could have been sampled)		
int drops (packets dropped due to a lack of resources)		
int input (SNMP ifIndex of input interface, 0 if not known)		
int output (SNMP ifIndex of output interface, 0 if not known) broadcast or multicast are handled as follows: the first bit indicates multiple destinations, the lower order bits number of interfaces		
int n * flow records		

↘ **Counter Sampling**

In counter sampling, an sFlow Agent periodically obtains the statistics and CPU usage on a specified interface. The statistics on the interface include the number of packets input through the interface and the number of packets output through the interface.

Figure 7-5 Counter Sample Header

## Functions and Features

Feature	Description
<u>Flow Sampling</u>	Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.
<u>Counter Sampling</u>	Periodically send the statistics on the interface to the sFlow Collector for analysis.

### 7.3.1 Flow Sampling

Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.

#### Working Principle

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet. Then, the sFlow Agent encapsulates the flow sampling data into an sFlow datagram and sends the datagram to the sFlow Collector for analysis.

### 7.3.2 Counter Sampling

Periodically send the statistics on the interface to the sFlow Collector for analysis.

#### Working Principle

The sFlow Agent performs interface polling on a regular basis. For an interface whose counter sampling interval expires, the sFlow Agent obtains the statistics on this interface, encapsulates the statistics into an sFlow datagram, and sends the datagram to the sFlow Collector for analysis.

## 7.4 Configuration

Configuration Item	Suggestion & Related Command	
<u>Configuring Basic Functions of sFlow</u>	 Mandatory configuration. Establish communication connections between sFlow Agent and sFlow Collector.	
	<b>sflow agent {address   interface}</b>	Configures the sFlow Agent address.
	<b>sflow collector collector-id destination</b>	Configures the sFlow Collector address.
	 Mandatory configuration. Enable flow sampling and counter sampling.	
	<b>sflow counter collector</b>	Enables the sFlow Agent to send counter samples to the sFlow Collector.
	<b>sflow flow collector</b>	Enables the sFlow Agent to send flow samples to the sFlow Collector .
<u>Configuring Optional Parameters of sFlow</u>	 Optional configuration. Sets the optional parameter attributes of sFlow.	
	<b>sflow collector collector-id max-datagram-size</b>	Configures the maximum length of the sFlow datagram.
	<b>sflow counter interval</b>	Configures the counter sampling interval.
	<b>sflow flow max-header</b>	Configures the maximum length of the packet header copied during flow sampling.
	<b>sflow sampling-rate</b>	Configures the sampling rate of flow sampling.
	<b>sflow source {address   interface}</b>	Configures the sFlow source address.

### 7.4.1 Configuring Basic Functions of sFlow

#### Configuration Effect

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

#### Notes

- Flow sampling can be configured on only physical interfaces.
- To enable the sFlow Collector to analyze the flow sampling results, the IP address of the sFlow Collector on the sFlow Agent device is required.

#### Configuration Method

##### ▾ Configuring sFlow Agent Address

- Mandatory configuration.
- Use the **sflow agent address** command to configure the address of the sFlow Agent.

- The sFlow Agent address must be a valid address. That is, the sFlow Agent address must not be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.

<b>Command Syntax</b>	<b>sflow agent { address { <i>ip-address</i>   ipv6 <i>ipv6-address</i> } } { interface { <i>interface-name</i>   ipv6 <i>interface-name</i> } }</b>
<b>Parameter Description</b>	<p><b>address</b>: Configures the IP address of the sFlow agent.</p> <p><i>ip-address</i>: sFlow Agent IPv4 address</p> <p><b>ipv6</b> <i>ipv6-address</i>: sFlow Agent IPv6 address</p> <p><b>interface</b>: Configures the interface of the sFlow agent.</p> <p><i>interface-name</i>: Interface of IPv4 address.</p> <p><b>ipv6</b> <i>interface-name</i>: Interface of IPv6 address.</p>
<b>Defaults</b>	No sFlow Agent address is configured by default
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	This command is used to configure the <b>Agent IP address</b> field in the output sFlow datagram. The datagram not configured with this field cannot be output. The sFlow Agent address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Agent address, a message indicating configuration failure is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

### ↘ Configuring sFlow Collector Address

- Mandatory configuration.
- Use the **sflow collector** command to configure the address of the sFlow Collector.
- The sFlow Collector address must be a valid address. That is, the sFlow Collector address must not be a multicast or broadcast address. sFlow Collector must exist, and the route to it must be reachable.

<b>Command Syntax</b>	<b>sflow collector collector-id destination { <i>ip-address</i>   ipv6 <i>ipv6_address</i> } udp-port [ [ vrf <i>vrf-name</i> ] ] [ oob ] [ via mgmt <i>mgmt-name</i> ] ] ] [ [ description <i>collector-name</i> ] ]</b>
<b>Parameter Description</b>	<p><i>collector-id</i>: sFlow Collector ID. The range is from 1 to 2.</p> <p><i>ip-address</i>: sFlow Agent IPv4 address. It is not configured by default</p> <p><b>ipv6</b> <i>ipv6-address</i>: sFlow Agent IPv6 address. It is not configured by default</p> <p><i>udp-port</i>: sFlow Collector listening port number</p> <p><b>vrf</b> <i>vrf-name</i>: VRF instance name. It is not configured by default</p> <p><b>oob</b>: The sampled traffics are output through the management interface. By default, this parameter is not configured.</p> <p><b>via mgmt</b> <i>mgmt-name</i>: Management port. It is not configured by default.</p> <p><b>description</b> <i>collector-name</i>: Description of the sFlow Connector. It is not configured by default.</p>
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	This command is used to configure the sFlow Collector address. The sFlow Collector address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Collector address, a message indicating configuration failure is displayed. The sFlow Collector monitors the sFlow datagram on the specified port. When the <b>vrf</b> parameter is configured, the corresponding VRF instance must exist. When you remove the a VRF instance, the sFlow Collector address will be removed if this VRF instance is also configured for an sFlow Collector address. When the <b>oob</b> parameter is configured, a datagram is sent to the sFlow Collector through

the management interface.
---------------------------

### ✚ Enabling sFlow Samples Output to the sFlow Collector

- Mandatory configuration.
- You can use the **sflow flow collector** command to enable the sFlow Agent to send flow samples to the sFlow Collector.
- This function must be enabled on the interface to send flow samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

<b>Command Syntax</b>	<b>sflow flow collector</b> <i>collector-id</i>
<b>Parameter Description</b>	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
<b>Defaults</b>	Sending the flow samples to the sFlow Collector is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Configuration Usage</b>	This command can be used for physical ports, SVI ports and sub routed ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

### ✚ Enabling Counter Samples Output to the sFlow Collector

- Mandatory configuration.
- You can use the **sflow counter collector** command to enable the sFlow Agent to send counter samples to the sFlow Collector.
- This must be enabled on the interface to send counter samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

<b>Command Syntax</b>	<b>sflow counter collector</b> <i>collector-id</i>
<b>Parameter Description</b>	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
<b>Defaults</b>	Sending counter samples to the sFlow Collector is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Configuration Usage</b>	This command can be used for physical ports, SVI ports and sub routed ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

### ✚ Enabling Counter Sampling and Flow Sampling

- Mandatory configuration.
- You can use the **sflow enable** command to enable the flow sampling and counter sampling on an interface.
- The forwarding performance of an interface may be affected after flow sampling is enabled.

<b>Command Syntax</b>	<b>sflow enable [ ingress [ acl <i>id</i>   <i>name</i> ]   egress ]</b>
<b>Parameter Description</b>	<b>ingress</b> : Enables sFlow sampling in ingress direction. <b>egress</b> : Enables sFlow sampling in egress direction. <i>id</i> : Indicates the ACL number. <i>name</i> : Indicates the ACL name.
<b>Defaults</b>	The sFlow sampling function on an interface is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Configuration Usage</b>	This command can be used to enable counter sampling and flow sampling for physical ports, SVI ports, and sub routed ports. If the direction parameter is not specified, sampling on both directions are enabled. The SVI ports and sub routed ports support only the <b>ingress</b> parameter. The ACL should be configured and applied on the interface before the flow sampling based on ACL matching is enabled. Up to two commands for ingress ACL-based flow sampling are supported on an interface.

**Check Method**

- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

**Configuration Examples**

▾ **Configuring Flow Sampling and Counter Sampling for sFlow Agent**

<b>Network Environment</b> Figure 7-6	
	As shown in Figure 7-6, start switch A that serves as the sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling traffic into sFlow datagrams at regular intervals or when the buffer is full, and send the sFlow datagrams to the sFlow Collector for traffic analysis.
<b>Configuration Method</b>	<ul style="list-style-type: none"> <li>● Configure 192.168.1.1 as the sFlow Agent address.</li> <li>● Configure 192.168.3.100 as the address of sFlow Collector 1, and 6343 as the port number.</li> <li>● Configure interface TenGigabitEthernet 0/1 to output flow samples and counter samples to sFlow Collector 1, and enable the sFlow sampling function on this interface.</li> </ul>
<b>Switch A</b>	<pre>FS# configure terminal FS(config)# sflow agent address 192.168.1.1</pre>

	<pre> FS(config)#sflow collector 1 destination 192.168.3.100 6343  FS(config)#interface TenGigabitEthernet 0/1  FS(config-if-TenGigabitEthernet 0/1)# sflow flow collector 1  FS(config-if-TenGigabitEthernet 0/1)# sflow counter collector 1  FS(config-if-TenGigabitEthernet 0/1)# sflow enable  FS(config-if-TenGigabitEthernet 0/1)# end                     </pre>
<p><b>Check Method</b></p>	<p>Use the <b>show sflow</b> command to check whether the command output is consistent with the configuration.</p>
	<pre> FS# show sflow  sFlow datagram version 5  Global information:  Agent IP: 192.168.1.1  sflow counter interval:30  sflow flow max-header:64  sflow sampling-rate:8192  Collector information:  ID  IP                      Port Size VRF 1   192.168.3.100            6343 1400 2   NULL                     0    1400  Port information  Interface          CID FID Enable TenGigabitEthernet 0/1      1    1    Y                     </pre> <p>Information displayed on the sFlowTrend software:</p>  <p>The preceding figure shows the TopN page of the sFlowTrend software. This page displays the flow sampling results and displays the top 5 source IP addresses that involve the largest traffic. The total incoming traffic is about 450 Kpps and the total outgoing traffic is 450 Kpps, which are consistent with the actual traffic.</p>

### 7.4.2 Configuring Optional Parameters of sFlow

#### Configuration Effect

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

#### Notes

- The forwarding performance may be affected when the sampling rate is too low.

#### Configuration Method

##### ▾ Configuring the Maximum Length of the Output sFlow Datagram

- Optional configuration.
- You can use the **sflow collector** command to configure the length of the sFlow datagram, excluding the Ethernet header, IP header, and UDP header. An sFlow datagram may contain one or multiple flow samples and counter samples. Configuration of the output sFlow datagram's maximum length may lead to the result that the number of sFlow datagrams output during processing of a certain number of flow samples differs from the number of sFlow datagrams output during processing of the same number of counter packets. If the maximum length is greater than MTU, the output sFlow datagrams will be segmented.

<b>Command Syntax</b>	<b>sflow collector</b> <i>collector-id</i> max-datagram-size <i>datagram-size</i>
<b>Parameter</b>	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2

<b>Description</b>	max-datagram-size <i>datagram-size</i> : maximum length of the outputsFlow datagram. The range is from 200 to 9,000.
<b>Defaults</b>	The default value is 1,400.
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	-

### ▾ Configuring the Flow Sampling Rate

- Optional configuration.
- You can use the **sflow sampling-rate** command to configure the global flow sampling rate.
- Configuration of flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate means a higher accuracy and larger CPU consumption. Therefore, the forwarding performance of the interface may be affected when the sampling rate is low.

<b>Command Syntax</b>	<b>sflow sampling-rate</b> <i>rate</i>
<b>Parameter Description</b>	<i>rate</i> : Sampling rate of sFlow sampling. One packet is sampled from every <i>n</i> packets ( <i>n</i> equals the value of <b>rate</b> ). The range is from 4,096 to 16,777,215.
<b>Defaults</b>	The default global flow sampling rate is 8,192.
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	This command is used to configure the global sampling rate of sFlow flow sampling, and sFlow flow sampling of all interfaces uses this sampling rate.

### ▾ Configuring the Maximum Length of the Packet Header Copied During Flow Sampling

- Optional configuration.
- You can use the **sflow flow max-header** command to configure the length of the packet header copied during flow sampling globally.
- Users can use this command to modify the datagram information to be sent to the sFlow Collector. For example, if a user concerns about the IP header, this user can configure the length to 56 bytes. During encapsulation of flow samples, the first 56 bytes of the sample packet are copied to the sFlow datagram.

<b>Command Syntax</b>	<b>sflow flow max-header</b> <i>length</i>
<b>Parameter Description</b>	<i>length</i> : maximum length of the packet header to be copied. The range is from 18 to 256.
<b>Defaults</b>	The default length of the packet header to be copied during global flow sampling is 64 bytes.
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	Configure the maximum number of bytes of the packet content copied from the header of the original packet. The copied content is recorded in the generated sample.

### ▾ Configuring the Sampling Interval

- Optional configuration.
- You can use the **sflow counter interval** command to configure the global counter sampling interval.
- Enable the counter sampling interface to send the statistics on it to the sFlow Collector at the sampling interval.

<b>Command Syntax</b>	<b>sflow counter interval</b> <i>seconds</i>
<b>Parameter Description</b>	<i>seconds</i> : time interval. The range is form 3 to 2,147,483,647. The unit is second.
<b>Defaults</b>	The default global counter sampling interval is 30 seconds.
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	This command is used to configure the global sFlow counter sampling interval, and sFlow Counter sampling of all interfaces uses this sampling interval.

### ▾ Configuring the sFlow Source Address

- Optional configuration.
- You can use the **sflow source { address | interface }** command to configure the sFlow Source address of the output packets.

<b>Command</b>	<b>sflowsource { address {<i>ip-address</i>   <b>ipv6</b> <i>ipv6-address</i> } } { interface { <i>interface-name</i>   <b>ipv6</b> <i>interface-name</i> } }</b>
<b>Parameter Description</b>	<p><b>address</b>: Configures the source IP address of sFlow output packets.</p> <p><i>ip-address</i>: sFlow Source IPv4 address</p> <p><b>ipv6</b> <i>ipv6-address</i>: sFlow Source IPv6 address.</p> <p><b>interface</b>: Configures the source interface of sFlow output packets</p> <p><i>interface-name</i>: sFlow Source interface (configured with an IPv4 address)</p> <p><b>ipv6</b> <i>interface-name</i>: sFlow Source interface (configured with an IPv6 address)</p>
<b>Defaults</b>	The default sFlow Source address is the local device IP address which is used to ping the destination IP.
<b>Command Mode</b>	Global configuration mode
<b>Configuration Usage</b>	This command is used to configure the source IP address of the output packets. If a source interface is specified, the primary address of the interface will be the source IP address of the outputs packets. If the source interface is not specified, for example, the interface is shutdown, the default source address will be used.

### Check Method

- Check whether an sFlow datagram with the flow samples is received on the sFlow Collector.
- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

### Configuration Examples

#### ▾ Configuring Optional Parameters of sFlow

<b>Network</b>	See Figure 7-6.
----------------	-----------------

<b>Environment</b>	
	<ul style="list-style-type: none"> <li>● Set the flow sampling rate to 4,096 in global configuration mode.</li> <li>● Configure the length of the packet header copied during flow sampling to 128 bytes in global configuration mode.</li> <li>● Set the sampling interval to 10 in global configuration mode.</li> </ul>
<b>Configuration Method</b>	<pre> FS# configure terminal FS(config)# sflow sampling-rate 4096 FS(config)# sflow flow max-header 128 FS(config)# sflow counter interval 10                     </pre>
	<p>Make traffic pass through interface TenGigabitEthernet 0/1.</p> <ul style="list-style-type: none"> <li>● Check whether there is traffic on interface TenGigabitEthernet 0/1 on sFlow Collector 1.</li> <li>● Use the <b>show sflow</b> command to check whether the command output is consistent with the configuration.</li> </ul>
<b>Check Method</b>	<pre> FS# show sflow  sFlow datagram version 5  Global information: Agent IP: 10.10.10.10 sflow counter interval:10 sflow flow max-header:128 sflow sampling-rate:4096  Collector information: ID  IP                      Port Size VRF 1   192.168.2.100            6343 1400 2   NULL                     0    1400  Port information Interface          CID FID Enable TenGigabitEthernet 0/1    0    1    B TenGigabitEthernet 0/2    0    1    I TenGigabitEthernet 0/3    0    1    E                     </pre>

## 7.5 Monitoring

### Displaying

Function	Command
Displays the sFlow configuration.	<b>show sflow</b>
Displays sFlow statistics.	<b>show sflow stats</b>

## 8 Configuring NETCONF

### 8.1 Overview

The Network Configuration Protocol (NETCONF) is a brand new Extensible Markup Language (XML)-based protocol proposed by the NETCONF working group of the Internet Engineering Task Force (IETF) in 2003. It can be used for device configuration, parameter retrieval, and monitoring and management. This protocol adopts the client/server communication mode, in which the protocol server program runs on the device while the protocol client program runs on clients. The XML format is used in packets of this protocol, including all configuration data and protocol messages. The NETCONF protocol consists of four layers: content layer, operation layer, Remote Procedure Call (RPC) layer, and transport layer. The content layer is a collection of managed data objects and configuration data of devices is stored at this layer. The operation layer is the basic primitive operation set applied to RPCs, such as <get>, <get-config>, <edit-config>, and <delete-config>. The RPC layer provides a simple mechanism unrelated to transport protocols, and the mechanism specifies elements of some error feedback messages. The transport layer provides a secure transport channel. The NETCONF protocol supports Secure Shell (SSH) (mandatory), Simple Object Access Protocol (SOAP), and Blocks Extensible Exchange Protocol (BEEP).

#### Protocols and Standards

- RFC4741: NETCONF Configuration Protocol
- RFC4742: Using the NETCONF Configuration Protocol over Secure Shell (SSH)
- RFC4743: Using NETCONF over the Simple Object Access Protocol (SOAP)
- RFC4744: Using the NETCONF Protocol over the Blocks Extensible Exchange Protocol (BEEP)
- RFC5277: NETCONF Event Notifications
- RFC5381: Experience of Implementing NETCONF over SOAP
- RFC5539: NETCONF Over Transport Layer Security (TLS)
- RFC5717: Partial Lock RPC for NETCONF
- RFC6022: NETCONF Monitoring Schema
- RFC6241: Network Configuration Protocol
- RFC6242: Using the Network Configuration Protocol over Secure Shell
- RFC6243: With-defaults capability for NETCONF
- RFC6470: NETCONF Notification Events
- RFC6536: NETCONF Access Control Model (NACM)
- RFC4741 and RFC4742 are replaced by RFC6241 and RFC6242 respectively.

### 8.2 Applications

Application	Description
NETCONF Network Device Management	Users send NETCONF configuration packets in the XML format to devices through network management software installed on a NETCONF client, to configure and manage the devices.

### 8.2.1 NETCONF Network Device Management

#### Scenario

As shown in the figure below, users can utilize the NETCONF network management software to manage and monitor network devices.

Figure 8-1

#### Deployment

The network management station and managed network devices are connected via networks. The SSH protocol needs to run on both the network management software and the devices. On the network management station, by using the NETCONF network management software, users can access the configuration databases and state databases on network devices, receive event notifications sent from the network devices, and manages and monitors the network devices.

## 8.3 Features

### Basic Concepts

#### ↘ Common Terms

- RFC: Remote Procedure Call
- DM: Data Model

#### ↘ Protocol Structure

The figure below shows the structure of the NETCONF protocol.

Figure 8-2 Structure of the NETCONF Protocol

▾ **Session Connection**

- NETCONF over SSH

The server listens to Port 830. An SSH channel needs to be established before the NETCONF protocol is used. The establishment of the SSH channel (SSH subsystem, named netconf) requires user authentication and negotiation of a range of transmission algorithms (including negotiation of keys, a compression algorithm, a hash algorithm, an encryption algorithm, and a signature algorithm).

Figure 8- 3 Packets Exchanged in a NETCONF Session

▾ **Capability Set Exchange**

Capability sets need to be exchanged after a channel is established. Both the server and client provide their implemented capability sets and ignore capabilities that are not understood or not implemented. Each peer must support at least the basic protocol capability

(urn:ietf:params:netconf:base:1.1). If the NETCONF protocol is compatible with an earlier protocol version, each peer should support the basic capability (urn:ietf:params:netconf:base:1.0) of this earlier version.

## ▾ Protocol Operations

Nine basic operation methods are defined for the operation layer of NETCONF and the operation methods are as follows: <get> and <get-config> are value acquisition operations, <edit-config>, <copy-config>, and <delete-config> are configuration operations, <lock> and <unlock> are lock protection operations provided in the case of concurrent operations on critical device resources (configuration files), and <close-session> and <kill-session> are session termination operations.

- <get>: Obtains the status and configuration data of a device.
- <get-config>: Obtains configuration data based on the filtering node in an RPC request.
- <edit-config>: Configures a device based on the provided data model definition and operation attributes. One important attribute **operation** can be set to **merge**, **replace**, **create**, **delete**, or **remove**, and the default value is **merge**.
- <copy-config>: Copies a configuration file, for example, copies a candidate configuration into a configuration file, copies a startup configuration into the running configuration, and writes a running configuration into the startup configuration. These copy operations need the target files to support the write capability.
- <delete-config>: Deletes a configuration file of a device. The running configuration file of a device cannot be deleted.
- <lock>: Provides lock protection for configuration data files. When a client is accessing (or modifying) a configuration data file of a device, other clients or non-NETCONF clients (such as SNMP or CLI clients) cannot access (or modify) the configuration data file.
- <unlock>: Unlocks a configuration data file.
- <close-session>: Closes the current session, including resource release, lock release, and disconnection. When this operation is performed, it must be ensured that the handling of the current service is complete and no new request is being handled.
- <kill-session>: forcibly terminates a session (the current session cannot be terminated), including resource release, lock release, and disconnection. When this operation is performed, an ongoing service must be terminated and uncompleted services must be rolled back to the state prior to service handling.

## Overview

Feature	Description
<u>Capability Set Exchange</u>	The NETCONF server and client mutually send capability sets to each other. The server (device) supports NETCONF 1.0 and NETCONF 1.1.
<u>&lt;get&gt;</u>	The client obtains configuration or state data of the device.
<u>&lt;get-config&gt;</u>	The client obtains configuration data of the device.
<u>&lt;edit-config&gt;</u>	The client modifies configuration data of the device.
<u>&lt;copy-config&gt;</u>	The client copies a configuration file on the device into another configuration file.
<u>&lt;delete-config&gt;</u>	The client deletes a configuration file on the device.
<u>&lt;close-session&gt;</u>	The client actively closes the current NETCONF session with the device.
<u>&lt;lock&gt;</u>	The client locks configuration files of the device.
<u>&lt;unlock&gt;</u>	The client unlocks the configuration files of the device.

### 8.3.1 Capability Set Exchange

The NETCONF client and NETCONF server exchange their capability sets immediately after establishing a connection. They can

perform subsequent data operations only when they support the same NETCONF protocol version. The format of sent packets is as follows:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
      urn:ietf:params:netconf:base:1.1
    </capability>
    <capability>
      Capability set 1
    </capability>
    <capability>
      Capability set 2
    </capability>
  </capabilities>
  <session-id>Session ID</session-id>
</hello>
```

 The capability exchange packet sent from the client to the server cannot contain the session ID (<session-id>) node.

Example of capability set exchange on the server:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
    <capability>urn:ietf:params:netconf:base:1.1</capability>
    <capability>urn:ietf:params:netconf:capability:writable-running:1.0</capability>
    <capability>urn:ietf:params:xml:ns:yang:ietf-yang-types?module=ietf-yang-types&revision=2013-07-15</capability>
    <capability>urn:FS:params:xml:ns:yang:FS-tacacs?module=FS-tacacs&revision=2016-10-25</capability>
    <capability>urn:FS:params:xml:ns:yang:FS-interfaces?module=FS-interfaces&revision=2016-10-25</capability>
    <capability>urn:ietf:params:xml:ns:yang:ietf-inet-types?module=ietf-inet-types&revision=2010-09-24</capability>
    <capability>urn:FS:params:xml:ns:yang:FS-openflow?module=FS-openflow&revision=2016-09-26</capability>
  </capabilities>
  <session-id>28</session-id>
</hello>
```

Example of capability set exchange on the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

### 8.3.2 <get>

This operation is used to obtain the configuration or state data of the device.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
```

```
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <filter type="subtree">
      Configuration data (or state data) filtering rule
    </filter>
  </get-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    Acquired configuration data (or state data)
  </data>
</rpc-reply>
```

If none of the subsets of state data on the device matches a filtering rule, the device returns a blank data node shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

### 8.3.3 <get-config>

This operation is used to acquire configuration data of the device. It acquires configuration data subsets based on various subtree filtering rules but cannot obtain the state data of the device.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      Protocol filtering rules
    </filter>
  </get-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    Acquired configuration data
  </data>
</rpc-reply>
```

If none of the subsets of configuration data on the device matches filtering rules, the device returns a blank data node shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

### 8.3.4 <edit-config>

This operation is used to edit the configuration based on the provided data model definition and operation attributes. The edit-config packets contain five operation attributes, which are specified in the operation attribute description of the configuration node in the delivered XML packets. The five attributes are as follows:

**merge:** Merges configuration data in edit-config packets that contain this attribute into a specified device configuration file (or database). If the configuration data does not exist, it is created based on delivered content.

**replace:** Uses configuration data in the edit-config packets that contain this attribute to replace a related configuration data node in a specified device configuration file (or database). If the configuration data does not exist, it is created based on delivered content. FS devices do not support this operation temporarily. If such an attribute is delivered, it is treated as the merge attribute.

**create:** Creates, in a specified configuration data file (or database), the configuration data in the edit-config packets that contain this attribute. If the configuration data does not exist, it is created based on delivered content. If the configuration data already exists, an rpc-error packet is returned and error-tag indicates that the data already exists.

**delete:** Deletes configuration data in the edit-config packets that contain this attribute from a specified configuration data file (or database). If the configuration data already exists, it is deleted directly. If the configuration data does not exist, an rpc-error packet is returned and error-tag indicates that the data is missing.

**remove:** Removes configuration data in the edit-config packets that contain this attribute from a specified configuration data file (or database). If the configuration data already exists, it is removed directly. If the configuration data does not exist, this operation is ignored and an OK response is returned.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <taFSet> <running/> </taFSet>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      Configuration data
    </config>
  </edit-config>
</rpc>
```

If a packet does not carry the error-option node, the value of this node is **stop-on-error** by default, indicating that once the configuration of a node in a packet is incorrect, subsequent configuration in the same packet is stopped and rpc-error is returned. If a packet does not carry the test-option node, the value of this node is **test-then-set** by default. If a packet does not carry the default-operation node, the value of this node is **merge** by default.

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
<ok/>
</rpc-reply>
```

If a packet carries the error-option node, the format is generally as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<edit-config>
  <taFSet> <running/> </taFSet>
  <error-option>behavior option in the case of a configuration error</error-option>
  <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
    Configuration data
  </config>
</edit-config>
</rpc>
```

The error-option node is a node of the enumeration type. It can be set to either of the following values:

stop-on-error: Stops the current edit-config operation immediately when the first error occurs. It is the default value of error-option. The configuration data before the error in the current configuration packet already takes effect.

continue-on-error: Continues processing configuration data even if an error occurs. Errors are recorded, and an error message is returned after all processing is completed (that is, rpc-error is returned for all configuration errors).

### 8.3.5 <copy-config>

This operation is used to synchronize startup configuration to running configuration.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <taFSet>
      <startup/>
    </taFSet>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

### 8.3.6 <delete-config>

This operation is used to delete the startup configuration of the device. The running configuration cannot be deleted.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
    <taFSet>
      <startup/>
    </taFSet>
  </delete-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

### 8.3.7 <close-session>

This operation is used to close the current session, release resources and locks, and break the connection.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <close-session/>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

### 8.3.8 <lock>

According to RFC6241, this operation is used to lock the configuration database (configuration files) and prevent multiple sources (such as the CLI, SNMP, and multiple concurrent NETCONF sessions) from modifying configuration files of the device concurrently, so as to avoid unnecessary configuration modifications. The device simplifies this operation, and can only prevent concurrent modifications (running configuration) from multiple NETCONF sessions and ensures modification security of configuration data.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <taFSet>
      <running/>
    </taFSet>
  </lock>
```

```
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

### 8.3.9 <unlock>

This operation is used to unlock the configuration database (configuration files; running configuration on the device here). <lock> and <unlock> are an operation pair.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <taFSet>
      <running/>
    </taFSet>
  </unlock>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

## 8.4 Configuration

Configure parameters related to SSH channel authentication before using NETCONF. For the SSH configuration, see *Configuring SSH*.

Configuration	Description and Command	
<u>Configuring the Candidate Capability of NETCONF</u>	 (Optional) It is used to configure the NETCONF server to feed back the candidate capability to the client when exchanging capabilities with the client.	
	<b>netconf capability candidate</b>	Enables the candidate and confirmed-commit capabilities of NETCONF.
<u>Configuring the Rollback Capability of NETCONF</u>	 (Optional) It is used to configure the NETCONF server to feed back the rollback-on-error capability to the client when exchanging capabilities with the client.	
	<b>netconf capability rollback</b>	Enables the rollback-on-error capability of NETCONF.
<u>Configuring the Validate Capability of NETCONF</u>	 (Optional) It is used to configure the NETCONF server to feed back the validate capability to the client when exchanging capabilities with the client.	

	<b>netconf capability validate</b>	Enables the validate capability of NETCONF.
Configuring DSCP for NETCONF Packets	 (Optional) It is used to configure the DSCP value for NETCONF packets.	
	<b>netconf dscp[ip ipv6]ssh value</b>	Configures the DSCP value for NETCONF packets.
Configuring the NETCONF Framework	 (Optional) It is used to configure the NETCONF framework.	
	<b>netconf enable</b>	Enables the NETCONF framework.
<u>Configuring the Feature Function of the YANG Module</u>	 (Optional) It is used to configure the NETCONF server not to feed back the feature attribute to the client when exchanging capabilities with the client.	
	<b>netconf feature-disable</b>	Disables the feature function of the NETCONF.
Configuring the Maximum Number of Returned Nodes from NETCONF Session	 (Optional) It is used to configure maximum number of returned nodes from NETCONF session. If the upper limit is exceeded, NETCONF will not return the nodes.	
	<b>netconf filter nodes-limit</b>	Configures the maximum number of returned nodes from NETCONF.
Configuring the Maximum Number of the NETCONF Session	 (Optional) It is used to configure maximum number of the NETCONF session. If the upper limit is exceeded, the connection between the NETCONF client and server will not succeed.	
	<b>netconf max-sessions</b>	Configures the maximum number of the NETCONF session.
Configuring the NETCONF Monitoring Port	 (Optional) It is used to configure a monitoring port for the connection between NETCONF server and client.	
	<b>netconf port</b>	Configures the NETCONF monitoring port.
<u>Configuring the YANG Module Multi-version Notification</u>	 (Optional) It is used to configure the server to advertise all versions of all supported YANG modules to the client when exchanging capabilities with the client.	
	<b>netconf yang multi-revision</b>	Configures the YANG module multi-version notification function of NETCONF.

#### 8.4.1 Configuring the Candidate Capability of NETCONF

##### Configuration Effect

The NETCONF server returns the candidate and confirmed-commit capabilities when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

##### Configuration Steps

##### 📌 Enabling the Candidate and Confirmed-Commit Capabilities of NETCONF

<b>Command</b>	<b>netconf capability candidate</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The candidate and confirmed-commit capabilities of NETCONF are disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Configuration Example

#### ▾ Enabling the Candidate and Confirmed-Commit Capabilities of NETCONF

<b>Scenario</b> Figure 8- 4	<p>NETCONF server                      NETCONF client</p> 
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the candidate and confirmed-commit capabilities of NETCONF.</li> </ul>
<b>NETCONF</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf capability candidate FS(config)#</pre>
<b>Verification</b>	N/A

### 8.4.2 Configuring the Rollback Capability of NETCONF

#### Configuration Effect

The NETCONF server returns the rollback capability when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

#### Configuration Steps

##### ▾ Enabling the Rollback Capability of NETCONF

<b>Command</b>	<b>netconf capability rollback</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The rollback capability of NETCONF is disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Configuration Example

#### ▾ Enabling the Rollback Capability of NETCONF

	Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf capability validate FS(config)#
<b>Verification</b>	N/A

#### 8.4.4 Configuring the DSCP of NETCONF Communication Packets

##### Configuration Effect

The NETCONF framework of the device allows STAs to configure the DSCP value of communication packets .

##### Configuration Steps

##### ✎ Configuring the DSCP Value of NETCONF Communication Packets

<b>Command</b>	<b>netconf dscp [ ip   ipv6 ] ssh <i>value</i></b>
<b>Parameter</b>	<i>value</i> : indicates the DSCP value. The range is from 0 to 63.
<b>Description</b>	By default, the TOS value of the TCP packets for SSH session is 0 and the TOS value of the NETCONF communication packets is 8.
<b>Defaults</b>	The NETCONF communication packet is not configured, and the TOS value of the TCP packets for SSH session is 0 and the TOS value of the NETCONF communication packets is 8.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

##### Configuration Example

##### ✎ Configuring the DSCP Value of NETCONF Communication Packets

<b>Scenario</b> Figure 8- 7	<p>NETCONF server                      NETCONF client</p> 
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the DSCP value of NETCONF communication packets.</li> </ul>
<b>NETCONF</b>	FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf dscp ip ssh 48 FS(config)#
<b>Verification</b>	N/A

#### 8.4.5 Enabling the NETCONF Framework

##### Configuration Effect

The NETCONF framework of the device allows STAs to connect to a configured port (port 830 by default).

### Notes

N/A

### Configuration Steps

#### ▾ Enabling the NETCONF Framework

<b>Command</b>	<b>netconf enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The NETCONF framework is enabled.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Verification

N/A

### Configuration Example

#### ▾ Enabling the NETCONF Framework

<b>Scenario</b> Figure 8-8	<p>NETCONF server                      NETCONF client</p> 
<b>Configuration Steps</b>	Enable the NETCONF framework.
<b>NETCONF</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf enable FS(config)#</pre>
<b>Verification</b>	N/A

## 8.4.6 Configuring the Feature Function of the YANG Module

### Configuration Effect

The NETCONF server does not return the feature attribute of the YANG module when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

### Configuration Steps

#### ▾ Disabling the Feature Attribute of NETCONF

<b>Command</b>	<b>netconf feature-disable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The feature attribute of NETCONF is enabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Configuration Example

#### ▾ Disabling the Feature Attribute of NETCONF

<b>Scenario</b> Figure 8-9	<p>NETCONF server                      NETCONF client</p> 
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Disable the feature attribute of the YANG module.</li> </ul>
<b>NETCONF</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf feature-disable FS(config)#</pre>
<b>Verification</b>	N/A

### 8.4.7 Configuring the Maximum Number of the Returned Nodes from NETCONF Session

#### Configuration Effect

The NETCONF client can only return the supported maximum number of XML nodes, or else, the client returns error.

#### Notes

This configuration takes effect only on the search result whose target is running.

#### Configuration Steps

#### ▾ Configuring the Maximum Number of the Returned Nodes from the NETCONF Session

<b>Command</b>	<b>netconf filter nodes-limit <i>num</i></b>
<b>Parameter</b>	<i>num</i> : indicates the maximum number of the returned nodes. The default value is 100000, and the value ranges from
<b>Description</b>	100 to 2147483647.
<b>Defaults</b>	The maximum number of the returned nodes is 100000.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

<b>Steps</b>	
<b>NETCONF</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf max-sessions 15 FS(config)#</pre>
<b>Verification</b>	<pre>FS (config)#show running-config   in max-sessions netconf max-sessions 15</pre>

### 8.4.9 Configuring the NETCONF Monitoring Port

#### Configuration Effect

Configure a port that a NETCONF client can connect to.

#### Notes

N/A

#### Configuration Steps

##### ▾ Configuring the NETCONF Monitoring Port

<b>Command</b>	<code>netconf port num</code>
<b>Parameter Description</b>	<i>num</i> : Specifies a monitoring port, which is port 830 by default. The value ranges from <b>1025</b> to <b>65535</b> .
<b>Defaults</b>	The default monitoring port is port 830.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### Verification

N/A

#### Configuration Example

##### ▾ Configuring the NETCONF Monitoring Port

**Scenario** NETCONF server NETCONF client  
**Figure 8-12**

- Configure the NETCONF monitoring port.

#### Steps

<b>NETCONF</b>	<pre>FS# configure terminal Enter configuration commands, one per line. End with CNTL/Z. FS(config)# netconf port 1234</pre>
----------------	--

	FS(config)#
<b>Verification</b>	N/A

#### 8.4.11 Configuring NETCONF to Preferentially Support the OpenConfig YANG Model

##### Configuration Effect

Enable the device to load the OpenConfig YANG model when the NETCONF server starts.

##### Notes

- The **netconf yang suite openconfig** command takes effect only after the device restarts. The OpenConfig YANG model is supported once configured. Otherwise, the YANG model self-defined by FS is supported.
- The **no netconf yang suite openconfig** command takes effect only after the device restarts. In this case, the OpenConfig YANG model is not supported.
- After the command takes effect upon device restart, output of the **show running-config** command is configuration by executing the CLI command.

##### Configuration Steps

##### ▾ Configuring NETCONF to Preferentially Support the OpenConfig YANG Model

- Optional.
- The configuration takes effect only after the device restarts.

<b>Command</b>	<b>netconf yang suite openconfig</b>
<b>Parameter Description</b>	N/A
<b>Defaults</b>	The OpenConfig YANG model is disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

##### Verification

- Run the **show netconf yang-suite** command to display the currently effective YANG model supported by NETCONF and the currently configured YANG model (which may be ineffective and can take effect only after the device restarts).

##### Configuration Example

##### ▾ Configuring NETCONF to Preferentially Support the OpenConfig YANG Model

One-to-many Topology	Allows one device to report gRPC information to multiple servers.
----------------------	---

### 9.2.1 One-to-one Topology

#### Scenario

One tested device is connected to only one server and reports gRPC data to the server, as shown in Figure 9- 1.

Figure 9- 1 One-to-one Topology

<b>Remarks</b>	S: tested device for collecting gRPC information
	PC: gRPC server for receiving gRPC information

#### Deployment

- Ensure that PC1 is reachable by S.
- Enable the gRPC function on S.
- On S, configure the events to be reported to the server.

### 9.2.2 One-to-many Topology

#### Scenario

One tested device is connected to multiple servers and reports gRPC data to the servers simultaneously, as shown in Figure 9- 2.

Figure 9- 2 One-to-many Topology

<b>Remarks</b>	S: tested device for collecting gRPC information
	PC: gRPC server for receiving gRPC information

#### Deployment

- Ensure that PC1 and PC2 are reachable by S.
- Ensure that the IP addresses of PC1 and PC2 are different.
- Enable the gRPC function on S.
- On S, configure the events to be reported to the server.

## 9.3 Features

### Basic Concepts

#### ↘ gRPC

gRPC is a high-performance cross-language open-source RPC framework developed by Google. It complies with the HTTP/2 and protobuf3.x protocols.

#### ↘ Channel

A channel is established between a device and a server.

#### ↘ Stub

A stub is an object generated during the multiplexing of a channel.

 For more information about gRPC terms, visit <https://github.com/grpc/grpc>.

### Overview

Feature	Description
<a href="#">Enabling the gRPC Function</a>	Enables the gRPC service on the device. The device can serve as a gRPC server to receive authentication and acquisition event messages, or serve as a gRPC client to report gRPC data.
<a href="#">Supporting the gRPC Login and Logout Function</a>	Supports the login and logout operations initiated by a server.
<a href="#">Event Types Supported by gRPC</a>	Supports real-time events, periodical events, and acquisition events.
<a href="#">Configuring a Specified Interface to Send gRPC Packets</a>	Binds a specified interface to send packets.
<a href="#">Preconfiguring Servers and To-be-subscribed Events</a>	Preconfigures servers and to-be-subscribed events.
<a href="#">Preconfiguring Information About Login Users of the gRPC Servers</a>	Preconfigures information about login users of servers.

#### 9.3.1 Enabling the gRPC Function

Configure gRPC, start the gRPC client and gRPC server services, configure to-be-subscribed events for the device, and receive a subscribed event sent by the NETCONF manager, to complete the gRPC data reporting process.

#### Working Principle

The gRPC communication complies with the HTTP/2 protocol. A client initiates a request and a server responds to this request, to complete one data exchange. A data request can be initiated only by a client and one data exchange must end with a response of a server. See the figure below.

Figure 9- 3 gRPC Communication

- Configure the gRPC function on device S and start the gRPC client and gRPC server services.
- Device S receives an acquisition event message from the server and responds to the server with the acquisition event message result.
- The gRPC server service configured on device S waits for a subscribed event sent from the NETCONF manager.
- The gRPC client service configured on device S reports gRPC data to the gRPC server based on the subscribed event and waits for a response.

### 9.3.2 Supporting the gRPC Login and Logout Function

gRPC supports the login and logout operations initiated by a server.

#### Working Principle

Figure 9- 4 gRPC Login

- Configure the gRPC function on device S and start the gRPC server service.
- Device S receives a login message initiated by a server, conducts local authentication, and responds to the server with the login result.
- The gRPC server service configured on device S receives only acquisition events initiated by authenticated login servers.

Figure 9- 5 gRPC Logout

- Configure the gRPC function on device S and start the gRPC server service.

- Device S receives a logout message initiated by a server, deletes the local matched login information, and responds to the server with the logout result.
- The gRPC server service configured on device S no longer receives acquisition events initiated by the logged out servers.

### 9.3.3 Event Types Supported by gRPC

gRPC supports three types of events: real-time events, periodic events, and acquisition events.

#### Working Principle

**Real-time events:** Real-time events use an event triggering threshold as a condition for information collection. When the event triggering threshold is reached, the device collects information and reports the collected information to a server.

**Periodic events:** Information is collected on the device based on a time interval. When the interval arrives, the device collects information and reports the collected information to a server.

**Acquisition events:** An acquisition event is initiated by a server to query data at a time. After receiving the message, the device collects information and reports the collected information to the server.

### 9.3.4 Configuring a Specified Interface to Send gRPC Packets

#### Working Principle

After the NETCONF manager delivers a gRPC command to a device to create a channel, the device creates a socket before sending packets to the server, to perform the ping operation to test the availability of the path. The device sends gRPC data packets to the server only when the path is available. By default, the created socket randomly binds the source address of a port of the device to sending ping packets. When the server receives only packets from a specified source address, the path cannot become available after the default gRPC action is performed and gRPC data packets cannot be uploaded.

Therefore, bind a specified source address when a socket is created, to test the availability of the path. In this way, gRPC data packets can be uploaded correctly.

### 9.3.5 Preconfiguring Servers and To-be-subscribed Events

#### Working Principle

The device can precreate servers and to-be-subscribed events via commands, or a controller can be simulated to notify the device of servers and to-be-subscribed events via NETCONF.

The device can delete servers and subscribed events via commands, or a controller can be simulated to notify the device of servers and unsubscribed events via NETCONF.

### 9.3.6 Preconfiguring Information About Login Users of the gRPC Servers

#### Working Principle

The device can precreate login users of authenticated servers via commands, or a server can be simulated to initiate a login request, pass authentication, and save information about the login users.

The device can delete login users of authenticated servers via commands, or a server can be simulated to initiate a logout request and delete information about the login users.

## 9.4 Configuration

Configuration	Description and Command	
<a href="#">Enabling the gRPC Function</a>	 (Mandatory) It is used to enable the gRPC function. Subscription and data reporting are supported only after the gRPC function is enabled.	
	<b>grpc</b>	Creates the gRPC mode and enables the gRPC function.
<a href="#">Configuring the Authentication Mode and AAA Server Authentication Attributes of the gRPC Login and Logout Function</a>	 (Optional) It is used to configure the authentication mode and AAA server authentication attributes of the gRPC login and logout function when server login authentication is required.	
	<b>authen login {local   authentication <i>mlist</i>}</b>	Configures the authentication mode for server login.
	<b>authen aaa-config {retry <i>times</i>   timeout <i>second</i>}</b>	Configures the login retry count and timeout time for AAA server authentication.
<a href="#">Configuring Event Types Supported by gRPC</a>	 (Mandatory) It is used to configure specified subscribed events.	
	<b>subscr realtime enable</b>	Enables all subscribed real-time events of gRPC.
	<b>subscr sample enable</b>	Enables all subscribed periodic events of gRPC.
	<b>subscr-sample-interval <i>interval</i></b>	Sets the timer interval for periodic events.
<a href="#">Specifying a Specified Interface to Send gRPC Packets</a>	<b>subscr-source-interface</b>	Configures a specified interface to send gRPC packets.
	<b>reply-source-interface</b>	Configures a specified interface to send GET data.
<a href="#">Setting gRPC Data Response Timeout Time</a>	<b>reply-timeout</b>	Sets data response timeout time for the GET/SET operation.
<a href="#">Preconfiguring Servers and To-be-subscribed Events</a>	<b>user-server <i>ip-address port-id</i></b>	Preconfigures servers that can subscribe to events.
	<b>type <i>json-event value value</i></b>	Preconfigures to-be-subscribed events of a specified server.
<a href="#">Preconfiguring Information About Login Users of gRPC Servers</a>	<b>user-client <i>id user-name ip-address</i></b>	Preconfigures information about login users of gRPC servers.

### 9.4.1 Enabling the gRPC Function

#### Configuration Effect

- Enable the gRPC client and gRPC server services.

#### Notes

- Ensure the network connectivity between the device and a server.
- The port ID of the local gRPC server is 50051.

#### Configuration Steps

##### 📌 Enabling the gRPC Function

- Mandatory.
- Enable the gRPC function on each device in global configuration mode unless otherwise specified.

<b>Command</b>	<b>grpc</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The gRPC function is disabled by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Use this command to create a gRPC instance, enable the gRPC function, and enter the gRPC process configuration mode. The gRPC client and gRPC server services are created at the same time when the gRPC function is enabled. The gRPC client service uploads data to a server while the gRPC server service parses authentication messages and acquisition messages sent from a server.

**Verification**

- Run the **show grpc status** command to display the running time after the gRPC function is enabled.

**Configuration Example**

Only gRPC-related configuration is described.

**Enabling the gRPC Function**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9- 6 One-to-One Topology</b>	
<b>Configuration Steps</b>	Enable the gRPC function. Configure a WAN port.
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# exit S(config)# interface HundredGigabitEthernet 0/49 S(config-if-HundredGigabitEthernet 0/49)# ip address 192.168.1.1 255.255.255.252</pre>
<b>Verification</b>	Ping the server address and check whether the address can be pinged successfully. Check whether the gRPC function is enabled.
<b>S</b>	<pre>S# show grpc status</pre>

**9.4.2 Configuring the Authentication Mode and AAA Server Authentication Attributes of the gRPC Login and Logout Function**

**Configuration Effect**

- Set the authentication mode of the gRPC login and logout function to authentication-free mode, AAA local authentication, or AAA server authentication (the timeout time and retry count can be configured).

#### Notes

- The new-model mode needs to be enabled for AAA server authentication.
- The authentication-free mode is not recommended.
- It is not recommended to modify the timeout time and retry count.

#### Configuration Steps

##### ▾ Configuring the Authentication Mode of the gRPC Login and Logout Function

- Optional.
- Perform this configuration as required.
- Run the **authen login** command on a required device in gRPC process configuration mode unless otherwise specified.

<b>Command</b>	<b>authen login {local   authentication <i>mlist</i>}</b>
<b>Parameter</b>	<b>local:</b> Uses the local username library for authentication. It is the default authentication mode.
<b>Description</b>	<b>authentication:</b> Uses a specified AAA server list for authentication. <b><i>mlist</i>:</b> Indicates the name of an AAA list.
<b>Defaults</b>	Local login is configured by default, that is, the <b>authen login local</b> command is configured.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	After receiving a login request from a server, the device selects AAA local authentication, AAA server authentication, or authentication-free mode as required. When the authentication is successful, the device records the login user information, namely, the IP address and username of the server. The device responds only to acquisition event requests initiated by authenticated servers.

##### ▾ Configuring the AAA Server Authentication Attributes of the gRPC Login and Logout Function

- Optional.
- Perform this configuration as required.
- It is not recommended to modify this configuration on the device unless otherwise specified.

<b>Command</b>	<b>authen aaa-config {retry <i>times</i>   timeout <i>second</i>}</b>
<b>Parameter</b>	<b>retry:</b> Sets the retry count for AAA server authentication.
<b>Description</b>	<b><i>times</i>:</b> Indicates the retry count. The value ranges from <b>1</b> to <b>100</b> . <b>timeout:</b> Sets the timeout time for AAA server authentication. <b><i>second</i>:</b> Indicates the timeout time, in seconds. The value ranges from <b>0</b> to <b>300</b> and the value <b>0</b> indicates that the authentication is considered failed after an AAA server timeout message is received.
<b>Defaults</b>	The default retry count is 1 and the default timeout time is 4s.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	Use this command to configure the authentication retry count and timeout time for the AAA server authentication mode in the case of server login. It is not recommended to change the default retry count and timeout time. A large retry count or improper timeout time may result in AAA lockout for 15 minutes (you can run the <b>clear aaa local user lockout all</b>

command to clear the AAA lockout).

**Verification**

- Run the **show running** command to check whether the configuration is correct.

**Configuration Example**

- ✔ Only gRPC-related configuration is described.

▾ **Configuring the Authentication Mode of the gRPC Login and Logout Function**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9-7 One-to-One Topology</b>	
<b>Configuration Steps</b>	<p>Enable the gRPC function.</p> <p>Configure the new-model mode for AAA authentication and a mlist list named test.</p>
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# authen login authentication test</pre>
<b>Verification</b>	<p>Check whether the configuration is correctly saved.</p> <p>Check whether the device can be pinged successfully from the PC client.</p> <p>Check whether the PC client can conduct authentication and make records.</p>
<b>S</b>	<pre>S# show running S# show grpc client</pre>

**9.4.3 Configuring Event Types Supported by gRPC**

**Configuration Effect**

- Enable all subscribed real-time events of the device.
- Enable all subscribed periodic events of the device.
- Modify the timer time for periodic events.

**Notes**

- Events subscribed by the server take effect only after the specified subscribed events are configured on the device.

**Configuration Steps**

▾ **Enabling Subscribed Events of the Device**

- Mandatory.
- Run the **subscr realtime enable** command to enable all subscribed real-time events of the device.
- Run the **subscr sample enable** command to enable all subscribed periodic events of the device.

- Run the **show grpc channel [ counter ]** command to display real-time/periodic events subscribed by a server or to display statistics.

<b>Command</b>	<b>subscr [realtime   sample] enable</b>
<b>Parameter Description</b>	<b>realtime:</b> Indicates subscribed real-time events. <b>sample:</b> Indicates subscribed periodic events.
<b>Defaults</b>	Subscribed real-time/periodic events are disabled by default.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	After configuring to-be-subscribed events, the gRPC process waits for the NETCONF manager to send a subscribed event. When a received subscription message matches the local to-be-subscribed event, the gRPC process enables the function of reporting gRPC data of the event to the server. After the NETCONF manager sends an unsubscribed event, if the received unsubscription message matches the local to-be-subscribed event, the gRPC process disables the function of reporting gRPC data of the event to the server. If the gRPC process configures no to-be-subscribed event, the gRPC process performs no processing when receiving a subscribed or unsubscribed event from the NETCONF manager.

#### ↘ Configuring the Timer Interval for Periodic Events

- Optional.
- Perform this configuration as required.
- Run the **subscr-sample-interval** command on a required device in gRPC process configuration mode to modify the timer interval for periodic events unless otherwise specified.

<b>Command</b>	<b>subscr-sample-interval interval</b>
<b>Parameter Description</b>	<b>interval:</b> Indicates the locally configured interval for reporting periodic events, in seconds. The value ranges from <b>1</b> to <b>65535</b> and the default value is <b>10</b> . <b>millisecond:</b> Indicates the millisecond part in the locally configured interval for reporting periodic events. The value ranges from 0 to 999 and the default value is 0. This value plus <i>interval</i> is the actual reporting interval, which should not be smaller than 100 milliseconds.
<b>Defaults</b>	The default timer interval for periodic events is used by default.
<b>Configuration Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	After a subscribed periodic event of the device is enabled and the NETCONF manager sends the subscribed periodic event, the gRPC process starts a periodic event timer and sends gRPC data to the server that subscribes to the event. When the periodic event sent by the NETCONF manager does not carry the timer interval, the timer interval is determined by the <b>subscr-sample-interval</b> command. When the periodic event sent by the NETCONF manager carries the timer interval, this timer interval shall prevail.

#### ↘ Configuring the Suppression Time for Real-time Events

- Optional.
- Perform this configuration as required.
- Run the **subscr-realtime-interval** command on a required device in gRPC process configuration mode to modify the suppression time for real-time events unless otherwise specified.

<b>Command</b>	<b>subscr-realtime-interval {all interval   realtime json-event interval}</b>
----------------	---

<b>Parameter Description</b>	<p><b>all:</b> Indicates that the configuration takes effect on all real-time events.</p> <p><b>realtime:</b> Indicates that the configuration takes effect on a specific real-time event.</p> <p><i>json-event:</i> Indicates the type of the configured real-time event.</p> <p><i>interval:</i> Specifies the suppression interval for reporting data of real-time events, in milliseconds. The value ranges from <b>1</b> to <b>1000000</b> and real-time events are not suppressed by default.</p>
<b>Defaults Configuration Mode</b>	<p>Real-time events are not suppressed by default.</p> <p>gRPC process configuration mode</p>
<b>Usage Guide</b>	<p>After the device enables a subscribed real-time event, if the threshold of the event is triggered, real-time packets are generated and sent to the server that subscribes to the event. When the threshold is triggered frequently, a large number of packets are generated and sent to the server within a short period of time. Data of these packets may be the same but handling these packets greatly increases the overheads of the device and server. To prevent this case, run the <b>subscr-realtime-interval</b> command to suppress the generation of new packets for real-time events within a period of time.</p>

**Verification**

- Run the **show grpc subscr realtime** command to display subscribed real-time events.
- Run the **show grpc subscr sample** command to display subscribed periodic events.
- Run the **show grpc channel [counter]** command to display the IP address, port ID, and subscribed events of a server, or display various statistics.

**Configuration Example**

▾ **Enabling Subscribed Real-time Events of the Device**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9- 8 One-to-One Topology</b>	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the gRPC function (omitted).</li> <li>● Set the to-be-subscribed CLI configuration modification real-time event.</li> <li>● The NETCONF manager subscribes to the CLI configuration modification real-time event.</li> </ul>
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# subscr realtime enable</pre>

<b>Verification</b>	Run the <b>show grpc subscr realtime</b> command to display the number of servers that subscribe to the CLI configuration modification real-time event.  Run the <b>show grpc channel [ counter ]</b> command to display the IP addresses, port IDs, and subscribed events of the servers or various statistics.
<b>S</b>	S# show grpc subscr realtime S# show grpc channel counter

▾ **Enabling Subscribed Periodic Events of the Device**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9- 9 One-to-One Topology</b>	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the gRPC function (omitted).</li> <li>● Configure the to-be-subscribed DCB PFC periodic event.</li> <li>● The NETCONF manager subscribes to the DCB PFC periodic event.</li> </ul>
<b>S</b>	S(config)# grpc S(config-grpc)# subscr sample enable
<b>Verification</b>	Run the <b>show grpc subscr sample</b> command to display the number of servers that subscribe to the DCB PFC periodic event.  Run the <b>show grpc channel [ counter ]</b> command to display the IP addresses, port IDs, and subscribed events of the servers or various statistics.
<b>S</b>	S# show grpc subscr sample S# show grpc channel counter

▾ **Configuring the Timer Interval for Periodic Events**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9-10 One-to-One Topology</b>	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable the gRPC function (omitted).</li> <li>● Set the interval for periodically acquiring the subscribed periodic event to 10s.</li> </ul>

S	S(config)# grpc S(config-grpc)# subscr-sample-interval 10
Verification	Run the <b>show grpc subscr sample</b> command to display the timer interval of all subscribed periodic events.
S	S# show grpc subscr sample

#### Common Errors

#### 9.4.4 Configuring a Specified Interface to Send gRPC Packets

##### Configuration Effect

- gRPC uses the IP address of a specified interface to send packets.

##### Notes

- The bound interface needs to be up.
- An IP address needs to be configured for the bound interface.

##### Configuration Steps

#### ↘ Configuring a Specified Interface to Send Real-time and Periodic Data

- Optional.
- Perform this configuration as required.
- Run the **subscr-source-interface** command on a required device in gRPC process configuration mode unless otherwise specified.

### ▾ Configuring a Specified Interface to Send GET Data

- Optional.
- Perform this configuration as required.
- Run the **reply-source-interface** command on a required device in gRPC process configuration mode unless otherwise specified.

#### Verification

- Run the **show running** command to check whether the configuration is correct.

#### Related Commands

### ▾ Configuring a Specified Interface to Send GET Data

<b>Command</b>	<b>reply-source-interface</b> <i>interface-type interface-number</i>
<b>Parameter Description</b>	<i>interface-type interface-number</i> : Specifies the interface name.
<b>Defaults</b>	gRPC randomly specifies a source address to send GET data by default.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	By default, the GET data is sent from a random source interface. You can use this command to enable the server to receive packets from a specified interface only.

### ▾ Configuring a Specified Interface to Send Real-time and Periodic Data

<b>Command</b>	<b>subscr-source-interface</b> <i>interface-type interface-number</i>
<b>Parameter Description</b>	<i>interface-type interface-number</i> : Specifies the interface name.
<b>Defaults</b>	gRPC randomly specifies a source address to send real-time and periodic data by default.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	By default, the real-time and periodic data is sent from a random source interface. You can use this command to enable the server to receive packets from a specified interface only.

#### Configuration Example

- ✔ Only gRPC-related configuration is described.

### ▾ Binding a Specified Interface to Send gRPC Packets

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9-12 One-to-One Topology</b>	

<b>Configuration Steps</b>	Enable the gRPC function. Configure a WAN port.
<b>S</b>	<pre>S(config)# interface HundredGigabitEthernet 0/49 S(config-if-HundredGigabitEthernet 0/49)# ip address 192.168.1.1 255.255.255.252 S(config-if-HundredGigabitEthernet 0/49)# exit S(config)# grpc S(config-grpc)# subscri-source-interface HundredGigabitEthernet 0/49 S(config-grpc)# reply-source-interface HundredGigabitEthernet 0/49</pre>
<b>Verification</b>	Check whether the configuration is correctly saved. Ping the server address and check whether the address can be pinged successfully. Check whether the device and the server can communicate with each other properly.
<b>S</b>	<pre>S# show running S# show grpc channel</pre>

#### 9.4.5 Setting gRPC Data Response Timeout Time

##### Configuration Effect

- Set the data response timeout time for the device serving as the gRPC server.

##### Notes

- The value can be set based on actual scenarios. A smaller value may result in a timeout error when the GET operation involves time-consuming data.

##### Related Commands

##### ▾ Setting gRPC Data Response Timeout Time

- Mandatory.

<b>Command</b>	<b>reply-timeout</b> <i>interval</i>
<b>Parameter Description</b>	<i>interval</i> : Indicates the data response timeout time of the device serving as the gRPC server, in seconds. The default value is 10 and the value ranges from 1 to 300.
<b>Defaults</b>	The default value is 10 seconds.
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	After timeout time is set for the gRPC process and the collector delivers the GET/SET operation, the device returns a timeout error to the collector if it fails to obtain data within the timeout time.

##### Verification

- Run the **show running** command to check whether the configuration is correct.

##### Configuration Example

- ✓ Only gRPC-related configuration is described.

##### ▾ Setting gRPC Data Response Timeout Time

<b>Scenario</b>	The network communication between device S and PC1 is normal.
-----------------	---

<b>Figure 9-13</b> <b>One-to-One</b> <b>Topology</b>	
<b>Configuration Steps</b>	Enable the gRPC function. Set the gRPC data response timeout time.
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# reply-timeout 30</pre>
<b>Verification</b>	Check whether the configuration is correctly saved. Run a command to check whether the displayed timeout value is the same as the configured value.
<b>S</b>	<pre>S# show running</pre>

#### Common Errors

#### 9.4.6 Preconfiguring Servers and To-be-subscribed Events

##### Configuration Effect

- After servers and to-be-subscribed events are preconfigured, gRPC packets of related events can be reported to the servers.

##### Notes

- The address and port ID of a server need to be valid.
- To-be-subscribed events and parameters need to be correct and valid.

##### Configuration Steps

##### ▾ Preconfiguring a Server that Can Subscribe to Events

- Mandatory.

<b>Command</b>	<b>user-server</b> <i>ip-address</i> <i>port-id</i>
<b>Parameter</b>	<i>ip-address</i> : Indicates the server IPv4 address.
<b>Description</b>	<i>port-id</i> : Indicates the port ID of the server.
<b>Defaults</b>	N/A
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	Use this command to precreate a specified server channel and switch to the gRPC server subscription mode. The to-be-subscribed events of the channel can be configured in this mode. The device can precreate servers and to-be-subscribed events via commands, or a controller can be simulated to notify the device of servers and to-be-subscribed events via NETCONF. The device can delete servers and subscribed events via commands, or a controller can be simulated to notify the device of servers and unsubscribed events via NETCONF.

▾ **Preconfiguring To-be-subscribed Events**

- Mandatory.

<b>Command</b>	<b>type json-event value value</b>
<b>Parameter Description</b>	<p><i>json-event</i>: Indicates the type of an event. For details, see the output of the <b>show grpc subscr   include json</b> command.</p> <p><i>Value</i>: Configures the parameter value, that is, the threshold for real-time events and time interval for periodic events.</p> <p><i>value-extend</i>: Indicates the extension of <i>value</i>. This parameter is used to set the millisecond part in the interval for reporting periodic events. The value ranges from 0 to 999. This value plus <i>value</i> should not be smaller than 100 milliseconds.</p>
<b>Defaults</b>	N/A
<b>Command Mode</b>	gRPC server subscription mode
<b>Usage Guide</b>	Configure to-be-subscribed events and parameters for the channel, which should be consistent with the configuration on NETCONF.

**Verification**

- Run the **show running** command to check whether the configuration is correct.
- Run the **show grpc channel** command to check whether servers and to-be-subscribed events are correct.

**Configuration Example**

- ✓ Only gRPC-related configuration is described.

▾ **Preconfiguring Servers and To-be-subscribed Events**

<b>Scenario</b>	The network communication between device S and PC1 is normal.
<b>Figure 9-14 One-to-One Topology</b>	
<b>Configuration Steps</b>	<p>Enable the gRPC function.</p> <p>Configure a channel.</p> <p>Configure the subscription type.</p>
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# user-server 192.168.0.1 12345 S(config-grpc-us)# type 0x10000000 value 10</pre>
<b>Verification</b>	<p>Check whether the configuration is correctly saved.</p> <p>Ping the server address and check whether the address can be pinged successfully.</p> <p>Check whether the device and the server can communicate with each other properly.</p>

S	S# show running S# show grpc channel
---	---

### Common Errors

The threshold for real-time events ranges from **-1** to **100**, the time interval for periodic events ranges from **-1** to **65535**, and an existing type needs to be used. Otherwise, the configuration does not take effect and is not retained.

### 9.4.7 Preconfiguring Information About Login Users of gRPC Servers

#### Configuration Effect

- After information about the login user of a gRPC server is preconfigured, information can be correctly acquired for acquisition event requests initiated by the specified gRPC server.

#### Notes

- The server address needs to be valid.
- The ID of a login user needs to be unique.

#### Related Commands

##### ⌵ Preconfiguring Information About Login Users of the gRPC Server

- Mandatory.

<b>Command</b>	<b>user-client</b> <i>id user-name ip-address</i>
<b>Parameter</b>	<i>id</i> : Indicates the ID of a login user.
<b>Description</b>	<i>user-name</i> : Indicates the username (unrelated to the AAA library; there may be no login user). <i>ip-address</i> : Indicates the allowed address.
<b>Defaults</b>	N/A
<b>Command Mode</b>	gRPC process configuration mode
<b>Usage Guide</b>	The device can precreate login users of authenticated servers via commands, or a server can be simulated to initiate a login request, pass authentication, and save information about the login users. The device can delete login users of authenticated servers via commands, or a server can be simulated to initiate a logout request and delete information about the login users.

#### Verification

- Run the **show running** command to check whether the configuration is correct.
- Run the **show grpc client** command to display information about login users.

#### Configuration Example

- ✓ Only gRPC-related configuration is described.

##### ⌵ Preconfiguring Information About Login Users of the gRPC Server

<b>Scenario</b>	The network communication between device S and PC1 is normal.
-----------------	---

<b>Figure 9-15</b> <b>One-to-One</b> <b>Topology</b>	
<b>Configuration Steps</b>	<p>Enable the gRPC function.</p> <p>Configure information about the login user of a specified server.</p>
<b>S</b>	<pre>S(config)# grpc S(config-grpc)# user-client 12345 test-user 192.168.0.1</pre>
<b>Verification</b>	<p>Check whether the configuration is correctly saved.</p> <p>Ping the server address and check whether the address can be pinged successfully.</p> <p>Check whether information can be acquired for an acquisition event request initiated by the server.</p>
<b>S</b>	<pre>S# show running S# show grpc client</pre>

## 9.5 Monitoring

### Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistics of a server that can subscribe to gRPC events.	<b>clear grpc channel</b> [ <i>ip-address port-id</i> ] [ <b>counter</b> ]
Clears data of gRPC periodic events and real-time events.	<b>clear grpc subscr</b> [ <b>sample</b> ] [ <b>counter</b> ]

### Displaying

Description	Command
Displays the IP address, port ID, and subscribed events of a server or various statistics.	<b>show grpc channel</b> [ <b>counter</b> ]
Displays information about login users of gRPC servers.	<b>show grpc client</b>
Displays the running status of gRPC.	<b>show grpc status</b>
Displays the statuses and statistics of subscribed events on the device.	<b>show grpc subscr</b> [ <b>realtime</b>   <b>sample</b> ]

### Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs the gRPC function.	<code>debug grpc { all   event }</code>

## 10 Configuring IFA and PSR

### 10.1 Overview

The In-band Flow Analyzer (IFA) and Packet Statistics Report (PSR) provide the sampling function for traffic visualization. IFA can be used to accurately determine the path and forwarding delay of specific traffic, encapsulate such information into User Datagram Protocol (UDP) packets, and send the packets to a customer's server for analysis. PSR can be used to periodically sample the Management Information Base (MIB) of an interface and interface statistics, encapsulate such information into UDP packets, and send the packets to a customer's server.

#### Protocols and Standards

- FS proprietary protocol

### 10.2 Applications

Application	Description
<u>Traffic Visualization</u>	Samples interface traffic on a LAN, and sends sampling results to the server for traffic analysis, so as to achieve the network monitoring purpose.

#### 10.2.1 Traffic Visualization

##### Scenario

As shown in the figure below, the traffic visualization solution is configured to monitor the communication between server 1 and server 2. Network devices between the two servers are simplified as three devices shown in the figure, and the configuration of omitted intermediate devices is the same as that of switch 2. IFA sampling is enabled on switch 1, the sampling start device. IFA sampling packets have the Meta-date (MD) field added on the sampling start device switch 1, intermediate device switch 2, and sampling end device switch 3 in sequence, and switch 3 sends the packets to the IFA server for analysis.

Figure 10-1

#### Deployment

- Configure an IFA loopback port on switch 1, and configure an IFA sampling-associated ACL, sampling rate, MD field to be added to packets on the sampling interface.

- On switch 2, configure the sampling interface to add the MD field to packets.
- On switch 3, configure server information, and configure the sampling interface to add the MD field to packets.
- Configure PSR sampling on any switch to output the MIB and statistics of the sampling interface.

## 10.3 Features

### Basic Concepts

Using network devices as nodes and device interfaces as basic sampling units, traffic visualization utilizes hardware chips to sample and send information about traffic forwarding paths to the server for traffic monitoring. In this way, traffic status can be monitored in real time and traffic exceptions can be identified in a timely manner, thereby ensuring normal and stable network running. IFA sampling is to add information about specific traffic such as the path and timestamps to packets, encapsulate the packets into UDP packets, and send the UDP packets to the server for analysis. PSR sampling is to periodically observe information about specific interfaces.

### Overview

Feature	Description
<a href="#">IFA Sampling</a>	Processes packets that pass through interfaces and sends them to the server for processing.
<a href="#">PSR Sampling</a>	Sends MIB, buffer, and other information of an interface to the server periodically.

#### 10.3.1 IFA Sampling

Packets that pass through interfaces are processed and sent to the server for processing.

#### Working Principle

On a monitored network, the start device and end device of IFA monitoring can be selected as required and there may be multiple intermediate devices. On the start device, when packets pass through the IFA sampling interface, the interface conducts IFA sampling processing on ACL-matched packets based on the sampling configuration of the interface. The processing includes adding the INT probe header (probe mark, load length, SN, and other information) and MD field (device ID, ingress/egress information, and ingress/egress timestamp). The IFA function utilizes a loopback interface to forward packets tagged with the INT Probe header through the original ingress. The MD field also needs to be added to the packets when they pass through intermediate devices and the end device. The end device encapsulates IFA sampling results into UDP packets and sends them to the IFA server for analysis. The path and forwarding delay of specific traffic can be determined based on the MD field and other information in IFA packets.

#### 10.3.2 PSR Sampling

In PSR sampling, the MIB and statistics of an interface are sent to the server periodically.

#### Working Principle

PSR sampling is to upload the MIB (device information) and buffer information (interface status and packet transmission and receiving statistics) of an interface to the server. When the PSR sampling interval expires, the above-mentioned information of the interface is encapsulated into UDP packets and sent to the server for analysis.

## 10.4 Product Description

Currently, only N8560/NC8200 series devices can be used as the IFA end device. Therefore, only N8560/NC8200 series devices can encapsulate IFA sampling packets and send the encapsulated packets to a specified server.

Currently, only N8560/NC8200 series devices can be used as the IFA end device. Therefore, only N8560/NC8200 series devices support server information configuration and only one server can be configured.

Currently, only N8560/NC8200 series devices can be used as the IFA start device. Therefore, only N8560/NC8200 series devices support IFA ACL configuration for sampling.

Currently, only N8560/NC8200 series devices can be used as the IFA start device. Therefore, only N8560/NC8200 series devices support the configuration of the IFA host port.

Currently, N8560/NC8200 series devices do not support filtering of IFA sampling packets.

## 10.5 Configuration

Configuration	Description and Command	
Configuring IFA Basic Functions	 (Mandatory) It is used to establish the connection and communication between the IFA sampling end device and the server.	
	<b>ifa server <i>server-name</i> source</b>	Configures an IFA server.
	<b>ifa send-server <i>server-name</i> [ <i>acl id</i>   <i>name</i> ]</b>	Configures the name of the server to which IFA packets of an interface are to be sent, and ACL rules.
	 (Mandatory) It is used to enable the IFA sampling function.	
	<b>ifa set-loopback interface <i>interface-name</i></b>	Configures an IFA loopback interface.
	<b>ifa acl</b>	Configures an IFA sampling–associated ACL and sampling rate.
	<b>ifa set-header md</b>	Adds the MD field to the header of IFA sampling packets.
	 (Optional) It is used to filter IFA packets.	
	<b>ifa filter enable</b>	Filters IFA packets on an interface.

	<b>ifa host-port</b>	Configures an interface as the IFA server port.
	 (Optional) It is used to configure the address of an IFA device.	
	<b>ifa set-device</b>	Configures the address of an IFA device.
Configuring PSR Basic Functions	 (Mandatory) It is used to establish the connection and communication between a PSR sampling device and a PSR server.	
	<b>psr server server-name source</b>	Configures a PSR server.
	<b>psr send-server server-name</b>	Configures the name of the server to which PSR packets of an interface are to be sent.
	 (Optional) It is used to adjust the transmission interval and packet length of PSR sampling packets.	
	<b>psr interval seconds</b>	Configures the time interval for PSR sampling.
	<b>psr collect-interface numbers</b>	Configures the number of interfaces whose sampling information is to be encapsulated into PSR packets.

### 10.5.1 Configuring IFA Basic Functions

#### Configuration Effect

- The IFA sampling end device can communicate with the server.
- An interface processes packets that pass through the interface based on the sampling rate and sends the packets to the server for processing.

#### Configuration Steps

##### ▾ Configuring an IFA Server

- Mandatory.
- Configure IFA server information on an end device.
- Configure the **ifa send-server server-name** command on a specified interface of the same end device so that IFA sampling packets can be encapsulated and sent to the specified server.

<b>Command</b>	<b>ifa server server-name source ip-address port udp-port destination ip-address port udp-port</b>
<b>Parameter</b>	<i>server-name</i> : Indicates the name of an IFA server.
<b>Description</b>	<i>ip-address</i> : Specifies the source and destination IPv4 addresses of IFA encapsulated packets. <i>udp-port</i> : Specifies the server port.
<b>Defaults</b>	No IFA server is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to configure the source and destination addresses of IFA encapsulated packets. The addresses can be host addresses only. When a non-host address (such as a multicast address or broadcast address) is configured, a configuration failure occurs. The IFA server listens to a configured port.

##### ▾ Configuring the Name of the Server to Which IFA Packets of an Interface Are to Be Sent

- Mandatory.

- Configure the **ifa send-server server-name [ acl id | name ]** command on a specified interface of an end device so that IFA sampling packets of the interface are encapsulated and sent to the specified server.
- The IFA server information needs to be configured on the same end device so that IFA sampling packets can be encapsulated and sent to the specified server.

<b>Command</b>	<b>ifa send-server server-name [ acl id   name ]</b>
<b>Parameter</b>	<i>server-id</i> : Indicates the name of an IFA server.
<b>Description</b>	<i>id</i> : ACL number <i>name</i> : ACL name
<b>Defaults</b>	IFA packets are not sent by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and aggregation ports (APs). Packets can be sent to the IFA server only after the IP address of the IFA server is configured.  The ACL rule is optional configuration. All the IFA packets on the interface will be sent to the server when no ACL rule is configured. To send the IFA packets matching the ACL rule to the specified server, configure the ACL rule first, and then apply the rule on the interface.

#### ↘ Configuring an IFA Loopback Interface

- Mandatory.
- Configure a physical port on a start device as the IFA loopback port of the device.

<b>Command</b>	<b>ifa set-loopback interface interface-name</b>
<b>Parameter</b>	<i>interface-name</i> : Indicates an interface name.
<b>Description</b>	
<b>Defaults</b>	No IFA loopback interface is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports.

#### ↘ Configuring an IFA Sampling–Associated ACL and Sampling Rate

- Mandatory.
- Configure sampling rules on a start device.
- A smaller sampling rate indicates lower sampling accuracy.

<b>Command</b>	<b>ifa acl { id   name } rate rate</b>
<b>Parameter</b>	<i>id</i> : Indicates the ACL ID.
<b>Description</b>	<i>name</i> : Indicates the ACL name. <i>rate</i> : Indicates the sampling rate. The value ranges from <b>1</b> to <b>65535</b> and the default value is <b>1000</b> .
<b>Defaults</b>	IFA sampling is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and APs. It is used to configure an IFA sampling–associated ACL and sampling rate. Four sampling rules using different ACLs and sampling rates can be configured for one interface.

### ▾ Adding the MD Field to the Header of IFA Sampling Packets

- Mandatory.
- Complete this configuration on a device interface that needs IFA sampling.

<b>Command</b>	<b>ifa set-header md</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	No MD field is added to packets by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and APs. This command is required on the ports of the non-end hop device that forwards the IFA sampling packets. Otherwise, the IFA sampling packets may not be able to be re-encapsulated and sent to the server, or the packets information may be incomplete.

### ▾ Filtering IFA Sampling Packets on an Interface

- Optional.
- Complete this configuration on a device interface that needs IFA sampling.

<b>Command</b>	<b>ifa filter enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	IFA sampling packets are not filtered by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and APs.

### ▾ Configuring an Interface as the IFA Server Port

- Optional.
- Complete this configuration on a device interface connected to the IFA server.

<b>Command</b>	<b>ifa host-port</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	No interface is configured as the IFA server port by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and APs. The IFA server port can be configured only after the IFA server is configured.

### ▾ Configuring the Address of an IFA Device

- Optional.
- Complete this configuration on a device interface that needs IFA sampling.

<b>Command</b>	<b>ifa set-device</b>
<b>Parameter</b>	N/A

<b>Description</b>	
<b>Defaults</b>	The address of an IFA device is not configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Verification

- Run the **show run** command to display IFA configuration and check whether the displayed configuration is consistent with the actual configuration.

### Configuration Example

#### Configuring IFA Sampling

<b>Scenario</b> <b>Figure 10-2</b>	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● On the start device switch 1, configure TenGigabitEthernet0/1 as an IFA loopback interface, enable IFA sampling on the interface on the packet path, and configure the interface to add the MD field to packets.</li> <li>● On the intermediate device switch 2, configure the interface on the packet path to add the MD field to packets.</li> <li>● On the end device switch 3, configure the interface on the packet path to add the MD field to packets and configure IFA server information.</li> </ul>
<b>Switch 1</b>	<pre> FS# configure terminal FS(config)# access-list 100 permit ip any any FS(config)# ifa set-loopback interface TenGigabitEthernet 0/1 FS(config)# interface TenGigabitEthernet 0/13 FS(config-if-TenGigabitEthernet0/13)# ifa acl 100 rate 100 FS(config-if-TenGigabitEthernet0/13)# ifa set-header md FS(config-if-TenGigabitEthernet 0/13)# interface TenGigabitEthernet 0/14 FS(config-if-TenGigabitEthernet0/14)# ifa set-header md FS(config-if-TenGigabitEthernet 0/14)# end </pre>
<b>Switch2</b>	<pre> FS# configure terminal FS(config)# interface HundredGigabitEthernet0/1 FS(config-if-HundredGigabitEthernet0/1)# ifa set-header md FS(config-if-HundredGigabitEthernet0/1)# interface HundredGigabitEthernet0/2 FS(config-if-HundredGigabitEthernet0/2)# ifa set-header md FS(config-if-HundredGigabitEthernet0/2)# end </pre>
<b>Switch3</b>	<pre> FS# configure terminal FS(config)# ifa server server1 source 192.168.2.100 port 1000 destination 192.168.2.101 port 2000 FS(config)# interface TenGigabitEthernet 0/15 </pre>

## 10.5.2 Configuring PSR Basic Functions

### Configuration Effect

- The PSR sampling end device can communicate with the server.
- The PSR sampling end device sends statistics of an interface to the server based on the sampling time interval.

### Notes

- A very small sampling time interval may affect forwarding performance.

### Configuration Steps

#### ↘ Configuring a PSR Server

- Mandatory.
- Configure the **psr send-server server-name** command on a specified interface of the same end device so that PSR sampling packets can be encapsulated and sent to the specified server.

<b>Command</b>	<b>psr server server-name source ip-address port udp-port destination ip-address port udp-port</b>
<b>Parameter</b>	<i>server-id</i> : Indicates the name of a PSR server.
<b>Description</b>	<i>ip-address</i> : Specifies the source and destination IPv4 addresses of PSR encapsulated packets. <i>udp-port</i> : Specifies the server port.
<b>Defaults</b>	No PSR server is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to configure the source and destination addresses of PSR encapsulated packets. The addresses can be host addresses only. When a non-host address (such as a multicast address or broadcast address) is configured, a configuration failure occurs. The PSR server listens to a configured port.

#### ↘ Configuring the ID of the Server to Which PSR Packets of an Interface Are to Be Sent

- Mandatory.
- The PSR server information needs to be configured on the end device so that PSR sampling packets can be encapsulated and sent to the specified server.

<b>Command</b>	<b>psr send-server</b> <i>server-name</i>
<b>Parameter Description</b>	<i>server-id</i> : Indicates the name of a PSR server.
<b>Defaults</b>	PSR packets are not sent by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command can be configured only on physical ports and APs. Packets can be sent to the PSR server only after the IP address of the PSR server is configured.

#### ▾ Configuring the Time Interval for PSR Sampling

- Optional.
- The actual transmission interval is subject to the CPU usage.

<b>Command</b>	<b>psr interval</b> <i>seconds</i>
<b>Parameter Description</b>	<i>seconds</i> : Indicates the time interval, in seconds. The value ranges from <b>1</b> to <b>100</b> and the default value is <b>5</b> .
<b>Defaults</b>	5
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to configure the global time interval for PSR sampling. The PSR sampling of all interfaces uses this sampling interval.

#### ▾ Configuring the Number of Interfaces Whose Sampling Information Is to Be Encapsulated into PSR Packets

- Optional.
- This command affects the actual PSR packet length.

<b>Command</b>	<b>psr collect-interface</b> <i>numbers</i>
<b>Parameter Description</b>	<i>numbers</i> : Indicates the interface quantity. The value ranges from <b>1</b> to <b>100</b> , and the default value is <b>1</b> .
<b>Defaults</b>	The default value is 1.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to configure the number of interfaces whose sampling information is to be encapsulated into PSR packets.

#### Verification

- Run the **show run** command to display PSR configuration and check whether the displayed configuration is consistent with the actual configuration.

#### Configuration Example

##### ▾ Configuring PSR Sampling

<p><b>Scenario</b></p> <p>Figure 10-3</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>Configure PSR server information on any device on the network and enable PSR sampling on interfaces.</li> <li>Set the PSR sampling interval to 10s in global configuration mode.</li> </ul>
<p><b>Switch3</b></p>	<pre> FS# configure terminal FS(config)# psr server server1 source 192.168.2.100 port 1001 destination 192.168.2.101 port 2002 FS(config)# psr interval 10 FS(config)# psr collect-interface 2 FS(config)# interface TenGigabitEthernet 0/16 FS(config-if-TenGigabitEthernet0/16)# psr send-server server1 FS(config-if-TenGigabitEthernet 0/16)# end                     </pre>
<p><b>Verification</b></p>	<ul style="list-style-type: none"> <li>Run the <b>show run</b> command to check whether displayed information is consistent with the configuration.</li> <li>Check whether the server receives PSR sampling data from the TenGigabitEthernet 0/16 interface of switch 3 every 10s.</li> <li>Run the <b>show psr statistics</b> command to display statistics.</li> </ul> <pre> FS# show psr statistics Server id      Name      Statistic(pkts)  Applied interface ----- 1              server1  20426            Te0/16                     </pre>

## 10.6 Monitoring

### Clearing

Description	Command
Clears IFA statistics.	<b>clear ifa statistics</b>
Clears PSR statistics.	<b>clear psr statistics</b>

### Displaying

Description	Command
Displays IFA and PSR configuration.	<b>show run</b>
Displays IFA statistics.	<b>show ifa statistics</b>
Displays PSR statistics.	<b>show psr statistics</b>

## 11 Configuring IPFIX

### 11.1 Overview

The IP Flow Information eXport (IPFIX) is a standard protocol published by the Internet Engineering Task Force (IETF) for the measurement of flow information on networks. It standardizes the format of network traffic statistics so that network devices and servers from different vendors can interwork with each other.

Through IPFIX, users can learn about the current network situation, including the interface rate, traffic, and traffic of various applications. Then, network optimization, security detection, and traffic charging can be carried out based on the information.

#### Protocols and Standards

- RFC 5470: Architecture for IP Flow Information Export
- RFC 5472: IP Flow Information Export (IPFIX) Applicability
- RFC 5103: Bidirectional Flow Export Using IP Flow Information Export (IPFIX)
- RFC 5153: IP Flow Information Export (IPFIX) Implementation Guidelines
- RFC 5102: Information Model for IP Flow Information Export
- RFC 5101: Specification of the IP Flow Information Export (IPFIX) Protocol for the Exchange of IP Traffic Flow Information
- RFC 3917: Requirements for IP Flow Information Export
- RFC 3954: Cisco Systems NetFlow Services Export Version 9

### 11.2 Applications

Application	Description
<a href="#">Deploying IPFIX Sampling on a Network</a>	Deploy the IPFIX sampling function on a network to collect statistics on the network traffic.

#### 11.2.1 Deploying IPFIX Sampling on a Network

##### Scenario

Deploy the IPFIX sampling function on a network to collect statistics on the network traffic.

As shown in the figure below, statistics on the network traffic need to be collected.

Figure 11-1 IPFIX Sampling Application

<b>Remarks</b>	The server serves as the IPFIX server to analyze IPFIX information.
----------------	---

The router/layer-3 switch collects traffic information and sends the information to the IPFIX server.

## Deployment

- Enable the IPFIX sampling function on the egress of the router/layer-3 switch.
- Configure the output of IPFIX packets to the IPFIX server on the router/layer-3 switch.
-  The IPFIX server software is generally commercial software and ManageEngine NetFlow Analyzer is recommended.

## 11.3 Features

### Basic Concepts

#### ▾ IPFIX Sampling

A network device receives packets from one interface and sends them out through another interface. When IPFIX needs to analyze packets, it is necessary to specify the interface and inbound/outbound direction for packet statistics. This is called sampling. FS devices allow you to specify the interface for packet sampling in the inbound or outbound direction or in both directions.

#### ▾ IPFIX Flow

A network forwarding device forwards packets one after another based on the destination address of the packets. It does not need to know the relevance between these packets, which actually exists. For example, the packets may belong to the same TCP session.

A packet consists of a series of properties, such as the IP address and TCP port number. Different packets may share some identical properties. A succession of consecutive packets with some identical properties that pass through a detection point within a period of time is called one packet flow. Properties used to determine whether packets belong to the same flow are key properties of the flow. Packets with the same key properties belong to the same flow. These properties can be some fields in the IP packet header such as the source IP address, the ToS field, or any combination of these fields. In the IPFIX implementation on FS devices, one flow is jointly determined by the following key fields:

- Source IP address
- Destination IP address
- Source port number
- Destination port number
- Layer-3 protocol type
- ToS
- Index of the packet sampling interface

The seven key fields jointly determine a unique flow. Packets sharing the same seven fields belong to the same flow. A packet with even only one key field different from other packets belongs to a different flow. One flow also has other statistical fields, such as the number of packets, next-hop IP address, and total number of flow bytes. Flow information on FS devices also includes the following:

- Flow establishment time
- Flow transmission time
- Total number of packets
- Total number of bytes
- Start time of the first flow

- End time of the final flow
- Inbound interface index of the flow (for inbound sampling)
- Outbound interface index of the flow (for outbound sampling)
-  IPFIX flow described here is also known as IPFIX basic flow or main mode flow.

### 📄 IPFIX Flow Table

An IPFIX flow table stores information about measured IP flows. When receiving an IP packet, the device, based on its flow key fields in the packet, searches the main cache for records about the flow. If no record about the flow exists, the device creates a flow record and records the flow information. If records about the flow exist, the device updates flow statistics in the flow records, such as the number of packets and number of flow bytes. For flow information in the IPFIX flow table in FS devices, see the IPFIX flow section.

For example, the device receives the following packets in sequence:

First packet:

Source IP address	192.168.196.3
Destination IP address	218.30.66.101
Source port number	1000
Destination port number	80
Layer-3 protocol type	TCP
ToS	0x0
...	
Bytes	100
Time	2009/4/8 11:21:13

The flow table is empty. The device creates a new flow entry for the packet and records the flow information.

Input ifx	Gi 1/0	
Src ip	192.168.196.3	
Dst ip	218.30.66.101	
Pro	TCP	
src port	1000	
Dst port	80	
Tos	0	
Start time	2009/4/8 11:21:13	
Stop time	2009/4/8 11:21:13	
packet	1	
bytes	100	

Second packet:

Source IP address	192.168.196.3
Destination IP address	218.30.66.101
Source port number	2000
Destination port number	80
Layer-3 protocol type	TCP
ToS	0x0
Input logical interface	Gi 1/0

...	
Bytes	100
Time	2009/4/8 11:21:14

The second packet has a different source interface from the first packet and therefore, it belongs to a new flow. Then, the device creates a new flow entry for this packet and records the flow information.

Input ifx	Gi 1/0	Gi 1/0
Src ip	192.168.196.3	192.168.196.3
Dst ip	218.30.66.101	218.30.66.101
Pro	TCP	TCP
src port	1000	2000
Dst port	80	80
Tos	0	0
Start time	2009/4/8 11:21:13	2009/4/8 11:21:14
Stop time	2009/4/8 11:21:13	2009/4/8 11:21:14
packet	1	1
bytes	100	100

Third packet:

Source IP address	192.168.196.3
Destination IP address	218.30.66.101
Source port number	1000
Destination port number	80
Layer-3 protocol type	TCP
ToS	0x0
Input logical interface	Gi 1/0
...	
Bytes	100
Time	2009/4/8 11:21:15

The third packet has the same key fields as the first packet and belongs to the same flow as the first packet. The device updates information in the first flow entry.

Input ifx	Gi 1/0	Gi 1/0
Src ip	192.168.196.3	192.168.196.3
Dst ip	218.30.66.101	218.30.66.101
Pro	TCP	TCP
src port	1000	2000
Dst port	80	80
ToS	0	0
Start time	2009/4/8 11:21:13	2009/4/8 11:21:14 AM
Stop time	2009/4/8 11:21:15 AM	2009/4/8 11:21:14 AM
packet	2	1
bytes	200	100

**i** IPFIX flow table described here is also known as the IPFIX basic flow table or main mode flow table. It is used to store information about basicflows.

## Basic Functions of IPFIX

An IPFIX device provides the following basic functions:

1. Collecting statistics on flows: The device acquires packet properties from a received packet and searches the flow table based on the seven key fields. If no relevant flow records exist in the flow table, the packet belongs to a new flow. Then, the device creates a flow entry and collects statistics on the flow. If the packet belongs to a recorded flow, the device updates the flow statistics.
2. Exporting flow information to the server: The device sends flow statistics to the server for analysis at appropriate time.

**i** The IPFIX specification defines only how the IPFIX device exports flow records. The storage and analysis (implemented by the IPFIX server) of flow records are beyond the scope of the IPFIX specification.

### Overview

Feature	Description
IPFIX Flow Statistics	Creates an IPFIX flow table and collects statistics on traffic in the network.
IPFIX Flow Aging	Deletes flow records from the flow table and exports statistics to the server before deletion.
IPFIX Flow Export	Exports flow record statistics to the server.

#### 11.3.1 IPFIX Flow Statistics

The IPFIX flow statistics function module is used to create a flow table, extract information from packets, and collect statistics on traffic in the network.

#### Working Principle

Figure 11-2 IPFIX Flow Statistics Process on the Network Device

- A network device forwards packets normally. It receives a packet from an interface and sends it out through another interface.
- The IPFIX function module of the network device extracts relevant packet properties (such as the IP address and packet length) from the packet header.
- The device adds a timestamp to the packet for the purpose of recording the flow establishment time, flow transmission time, and duration.
- The device conducts sampling on packets according to the configuration. Sampling here refers to processing one packet out of every  $n$  packets. For example, 1:100 sampling rate indicates that one packet is selected for processing by subsequent modules in every 100 packets. If the configured sampling rate is 1:1, all packets will be processed.
- The device collects statistics on the flow. If no record about a flow exists, the device creates a flow record. If the flow record exists, the device updates flow information (such as the number of packets and number of bytes).
- Flow records will be deleted at specific time and exported to the IPFIX server.

### 11.3.2 IPFIX Flow Aging

Flow records in the flow table need to be deleted under certain circumstances, and the statistics need to be exported to the server before deletion. This process is called flow aging. Flow aging aims to avoid infinite growth of the flow table and ensure that the IPFIX server can receive flow statistics.

#### Working Principle

- When no packet belonging to a flow is received within a period of time (inactive aging time), the flow has aged and the flow information should be exported.
- A flow may last very long and its information cannot be recorded infinitely. Users can set a time (active aging time) for flow aging. When the duration of a flow exceeds the time, the flow should be aged.
- IPFIX-relevant configuration can be performed to age flow records.

If a flow entry is aged and deleted but a packet with the seven key fields same as the aged flow is received very soon, a new flow entry will be created for the packet because no entry about the flow exists in the flow table.

### 11.3.3 IPFIX Flow Export

IPFIX flow export refers to exporting aged flow records to the IPFIX server, which analyzes flow records.

#### Working Principle

After aging, flow records need to be exported to the server. In this case, the flow record will be encapsulated into a UDP or TCP packet in the format defined in IPFIX and sent to the configured server. The collector on the server will process the record. The collector is a special software tool for processing flow records. It can visually display the current network status and analyze network traffic based on received flow records.

The IPFIX device transmits flow records by using a template. Before transmitting flow records, the device generates a template in the flow record format and sends it to the server regularly. The template defines properties and length of fields in the flow record. IPFIX has defined up to hundreds of field properties and each property has an identifier to mark its meaning. For example, identifier 8 indicates the source IP address. After receiving the template, the server knows the format of the subsequent flow record from the template, and interprets the IPFIX flow record based on the flow record format defined in the template. The template and flow record can be stored in the same packet or one packet can contain multiple flow records or templates.

The IPFIX device can send only important properties of a flow. The server software can extract only useful flow properties from flow records and ignore other properties. For example, FS devices consider the TCP flag useful for network security analysis, and carry the TCP flag in exported flow information. But some server software is used for traffic analysis only and does not support network analysis, and therefore ignores the TCP flag. There is no compatibility issue between the device and server.

Likewise, when a network device adds new fields (flow properties) to flow records, the network device needs to only re-create a data template. The server interprets flow records based on the new template, with no need to upgrade the server software, greatly enhancing the scalability.

The following uses UDP as an example to describe the IPFIX template and data.

Figure 11-3 IPFIX Packet

As shown in the figure above, an IPFIX packet contains a template and flow records. An IPFIX header is added to the front of the IPFIX packet and is transmitted over UDP.

Figure 11-4 IPFIX Template and Data

The IPFIX template format is described as follows:

FlowSet ID = 2 indicates that subsequent content is a template, which defines the format of flow records.

Length indicates the template length.

Template ID = 256 indicates that subsequent content is the format of a flow record of type 256.

Field Num indicates the number of fields composing a flow record format.

Field n type indicates the meaning of field N in the flow record. The meaning of each value is defined in detail in the IPFIX specification. For example, Field 1 type = 21 defines that the first field of a flow record indicates the flow establishment time.

Field n length indicates the number of bytes of field N in the flow record. For example, Field 1 length = 4 defines that the first field of a flow record indicates the flow establishment time and the value occupies four bytes.

A template can define the format of a flow record, including the number of fields composing the template, meaning of each field, and data bitwidth.

Description of the IPFIX data format:

Flow Set ID = 256 indicates that subsequent content is a flow record and the record is interpreted according to template 256.

Length indicates the data length.

Field n Value indicates the value of field N in the flow record. For example, Field 1 Value = 12:30 indicates that the flow establishment time is 12:30 and occupies four bytes (the meaning and bit width have been defined in the template).

## 11.4 Configuration

Configuration	Description and Command	
Configuring the IPFIX Flow Statistics Function	 (Mandatory) It is used to enable IPFIX sampling.	
	<b>{ ip } flow ingress</b>	Enables the IPFIX function in the inbound direction of an interface.
	<b>{ ip } flow egress</b>	Enables the IPFIX function in the outbound direction of an interface.
	<b>flow-sampler <i>sampler-map-name</i> [ egress ]</b>	Configures the sampling rate rule on an interface.
	<b>flow-sampler-map <i>sampler-map-name</i></b>	Enters the sampling rate rule configuration mode.
	<b>mode random one-out-of <i>packet-interval</i></b>	Configures the sampling rate rule.
Configuring the Export of Main Mode Flow Records	 (Mandatory) It is used to configure the export of IPFIX flow records.	
	<b>{ ip   ipv6 } flow-export destination</b>	Configures the address of the server, to which flow records are to be exported.
	<b>{ ip   ipv6 } flow-export version</b>	Configures the format for packets to be exported.
	<b>{ ip   ipv6 } flow-export source</b>	Configures the source interface for exporting packets.
	<b>{ ip   ipv6 } flow-export template</b>	Configures parameters relevant to an export template.
Configuring Parameters for the Main Mode Flow Table	 (Optional) It is used to configure parameters for the IPFIX main mode flow table.	
	<b>{ ip   ipv6 } flow-cache timeout</b>	Configures the aging time of flow records.

### 11.4.1 Configuring the IPFIX Flow Statistics Function

#### Configuration Effect

- Collect statistics on IPv4 traffic on the network.
- Collect statistics on IPv6 traffic on the network.

#### Notes

N/A

#### Configuration Steps

##### ➤ Enabling the IPFIX Function in the Inbound Direction of an Interface

- Mandatory.

- Run the **{ ip } flow ingress** command on a specified interface to enable the IPFIX function in the inbound direction of the interface.

<b>Command</b>	<b>{ ip } flow ingress</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The IPFIX function is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	N/A

#### ▾ Enabling the IPFIX Function in the Outbound Direction of an Interface

- Mandatory.
- Run the **{ ip } flow egress** command on a specified interface to enable the IPFIX function in the outbound direction of the interface.

<b>Command</b>	<b>{ ip } flow egress</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Defaults</b>	The IPFIX function is disabled by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	N/A

#### ▾ Entering the Sampling Rate Rule Configuration Mode

- Mandatory.
- In global configuration mode, run the **flow-sampler-map *sampler-map-name*** command to enter the sampling rate rule configuration mode and then configure sampling rate rules.
- If you enter the sampling rate rule configuration mode but do not configure sampling rate rules, the **show run** command will not show the sampling rate rule configuration mode.

<b>Command</b>	<b>flow-sampler-map <i>sampler-map-name</i></b>
<b>Parameter</b>	<i>sampler-map-name</i> : Indicates the name of a sampling rate rule.
<b>Description</b>	
<b>Defaults</b>	No sampling rate rule is configured by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command is used to enter the sampling rate rule configuration mode.

#### ▾ Configuring the Sampling Rate Rule

- Mandatory.
- In sampling rate rule configuration mode, run the **mode random one-out-of *packet-interval*** command to configure a sampling rate rule, that is, to conduct sampling once every *packet-interval* packets.
- You need to run the **flow-sampler *sampler-map-name* [egress]** command on a specified interface for the sampling rate rule to take effect on the interface.

<b>Command</b>	<b>mode random one-out-of</b> <i>packet-interval</i>
<b>Parameter Description</b>	<i>packet-interval</i> : Indicates the sampling interval, that is, sampling is conducted once every <i>packet-interval</i> packets.
<b>Defaults</b>	No random sampling rate rule is defined by default.
<b>Command Mode</b>	Sampling rate rule configuration mode
<b>Usage Guide</b>	N/A

### ▾ Applying the Sampling Rate Rule Configuration to an Interface

- Mandatory.
- Run the **flow-sampler** *sampler-map-name* [ **acl { id | name }** | **egress** ] command on a specified interface to enable the IPFIX function in the inbound/outbound direction of the interface and collect statistics on incoming/outgoing traffic of the interface.

<b>Command</b>	<b>flow-sampler</b> <i>sampler-map-name</i> [ <b>acl { id   name }</b>   <b>egress</b> ]
<b>Parameter Description</b>	<i>sampler-map-name</i> : Indicates the name of a sampling rate rule. <b>egress</b> : Indicates the outbound direction. The rule is applied to the inbound direction if no direction is specified. <i>id</i> : Indicates the ACL ID. <i>name</i> : Indicates the ACL name.
<b>Defaults</b>	No sampling rate rule is applied to an interface by default.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	An ACL is applied only to inbound sampling by default. That is, if an ACL is configured or <b>egress</b> is not specified, the configured sampling rate rule is applied to inbound sampling. Configure an ACL before applying a sampling rate rule. After the ACL is applied to an interface, sampling is conducted on packets matching the ACL.

### Verification

- Run the **show ip flow interface** command to display the IPFIX configuration of an interface.
- Run the **show { ip | ipv6 } flow cache** command to display flow table information of the device.

### Configuration Example

#### ▾ Configuring the IPFIX Sampling Function

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Interface GigabitEthernet 1/1 is connected to the Internet and the Internet traffic needs to be monitored and analyzed.</li> <li>● Enable the IPFIX function on interface GigabitEthernet 1/1.</li> </ul>
	<pre> FS# config terminal FS(config-sampler)# mode random one-out-of 10000 FS(config-sampler)# exit FS(config)# interface gigabitEthernet 1/1 FS(config-if)# flow-sampler my-sampler  Or FS(config-if)# flow-sampler my-sampler egress </pre>

	<pre>FS(config-if)# ip flow ingress FS(config-if)# ip flow egress</pre>
<b>Verification</b>	<ul style="list-style-type: none"> <li>● Run the <b>show ip flow interface</b> command to display the interface configuration.</li> <li>● Generate traffic on interface gigabitEthernet 1/1. If the <b>ip flow ingress</b> command is configured, statistics on incoming traffic of interface gigabitEthernet 1/1 are collected. If the <b>ip flow egress</b> command is configured, statistics on outgoing traffic of interface gigabitEthernet 1/1 are collected. Run the <b>show ip flow cache</b> command to check traffic statistics.</li> </ul>
	<pre>FS# show ip flow interface interface GigabitEthernet 1/1     flow-sampler my-sample flow-sampler my-sampler egress     ip flow ingress     ip flow egress</pre>

### Common Errors

N/A

## 11.4.2 Configuring the Export of Main Mode Flow Records

### Configuration Effect

- Send aged main mode flow records to the server.

### Notes

- The route to the configured address of the server, to which flow records are to be exported, must be reachable. Otherwise, the **show { ip | ipv6 } flow export** command displays nothing.
- If the type of interface used for exporting flow records is changed from port to VLAN and the interface is an SVI, you also need to configure IPFIX on the VLAN interface.

### Configuration Steps

#### 📌 Configuring the Address of the Server, to Which Flow Records Are to Be Exported

- Mandatory.
- You can run the **{ ip | ipv6 } flow-export destination** command to export aged flow records to the IPFIX server.
- A maximum of two IPFIX servers can be configured for record output.

<b>Command</b>	<b>{ ip   ipv6 } flow-export destination { ipv6 ipv6_addr   ip-address   hostname } udp-port [ [ vrf vrf-name ] ] [ oob [ via mgmt mgmt-name ] ] ]</b>
<b>Parameter</b>	<b>ipv6 ipv6_addr</b> : Sets an IPv6 address of the server, to which flow records are to be exported.
<b>Description</b>	<p><b>ip-address</b>: Sets an IPv4 address of the server, to which flow records are to be exported.</p> <p><b>hostname</b>: Sets a domain name of the server, to which flow records are to be exported.</p> <p><b>udp-port</b>: Indicates the ID of the server port used for monitoring IPFIX packets.</p>

	<p><b>vrf <i>vrf-name</i></b>: Indicates the name of the VRF instance, to which the server address belongs.</p> <p><b>oob</b>: Indicates that sampled packets are exported from the management port. It is not configured by default.</p> <p><b>mgmt <i>mgmt-name</i></b>: <b>Indicates the name of the management port for exporting sampled packets. It is not configured by default.</b></p>
<b>Defaults</b>	IPFIX flow records are not exported to the server by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	IPFIX flow records of IPv4 and IPv6 protocol packets can be exported to a server with either an IPv4 or IPv6 address.

### ↘ Configuring the Format for Packets to Be Exported

- Optional.
- Run the **{ ip | ipv6 } flow-export version** command to specify the format of packets to be exported.

<b>Command</b>	<b>{ ip   ipv6 } flow-export version { 9   10 }</b>
<b>Parameter Description</b>	<p><b>version 9</b>: Indicates that the format of to-be-exported packets complies with the Netflow V9 standard.</p> <p><b>version 10</b>: Indicates that the format of to-be-exported packets complies with the IETF standard.</p>
<b>Defaults</b>	The <b>version10</b> packet format is adopted by default.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### ↘ Configuring the Source Interface for Exporting Packets

- Optional.
- Perform the configuration when aged flow records need to be exported to the server and the source IP address of packets needs to be specified.

<b>Command</b>	<b>{ ip   ipv6 } flow-export source <i>interface-name</i></b>
<b>Parameter Description</b>	<b>source <i>interface-name</i></b> : Indicates the interface name.
<b>Defaults</b>	By default, the local interface address that best-matches the server address is adopted.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>This command is used to configure the source IP address for packets to be exported. The default source address of IPFIX packets to be exported is the local address that best-matches the server address. When the source interface is specified, the source address of the IPFIX packets to be exported is the main address of the interface (the IPv6 address is the first global IPv6 address of the interface).</p> <p>When no source interface is specified, the source address of the IPFIX packets to be exported is the local address that best-matches the server address. The server address can be an IPv4 or IPv6 address or both. If the source interface is specified and the server address is set to an IPv6 address, ensure that an IPv6 address is configured for the source interface. If the server address is set to an IPv4 address, ensure that an IPv4 address is configured for the source interface. Otherwise, the system obtains the best-matched local address as the source address based on the server address. You must ensure that the source interface and the server, to which flow records are to be exported, belong to the same VRF instance. Otherwise, the system obtains the best-matched local address as the source address based on the server address.</p>

### ▾ Configuring Parameters Relevant to an Export Template

- Optional.
- Perform the configuration when the template export frequency needs to be adjusted. The IPFIX server parses IPFIX packets according to the template. When the IPFIX function is enabled on the device at the first start, you can set the template retransmission frequency to a smaller value so that the IPFIX server can receive the IPFIX template soon, for example, set the retransmission interval to 1 minute.

<b>Command</b>	<b>{ ip   ipv6 } flow-export template { refresh-rate <i>packets</i>   timeout-rate <i>minutes</i>   options { export-stats   refresh-rate <i>packets</i>   timeout-rate <i>minutes</i> }   model <i>model-id</i> }</b>
<b>Parameter Description</b>	<p><b>refresh-rate <i>packets</i></b>: Specifies the template retransmission frequency, with the unit of packets. The value ranges from 1 to 600 and the default value is 20.</p> <p><b>timeout-rate <i>minutes</i></b>: Specifies the template retransmission interval, with the unit of minutes. The value ranges from 1 to 3600 and the default value is 10.</p> <p><b>options export-stats</b>: Enables the export of option packets.</p> <p><b>options refresh-rate <i>packets</i></b>: Sets the retransmission frequency of option data, with the unit of packets. The value ranges from 1 to 600. The default value is 20.</p> <p><b>options timeout-rate <i>minutes</i></b>: Sets the retransmission interval of option data. The value ranges from 1 to 3600. The default value is 10 minutes.</p> <p><b>model <i>model-id</i></b>: Indicates the template mode ID. The value can be 0 or 1 and the default value is 0. Template mode 0 indicates that an inbound sampling template and an outbound sampling template exist. Template mode 1 indicates that the sampling direction is not differentiated and statistics in the inbound and outbound directions are recorded in the same template.</p>
<b>Defaults</b>	The default data template retransmission frequency is 20 packets and the default retransmission interval is 10 minutes.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Verification

Run the **show { ip | ipv6 } flow export** command to display information on the IPFIX server.

### Configuration Example

#### ▾ Configuring the Server, to Which Flow Records Are to Be Exported

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure the output destination address and destination port.</li> <li>● Configure the format for packets to be exported.</li> <li>● Configure the output template retransmission frequency.</li> <li>● Configure output options.</li> </ul>
	<pre> FS# config terminal FS(config)# ip flow-export destination 192.168.2.2 9996 FS(config)# ip flow-export source gigabitEthernet 4/2 FS(config)# ip flow-export version 9 FS(config)# ip flow-export template refresh-rate 30 </pre>

	<pre>FS(config)# ip flow-export template timeout-rate 40 FS(config)# ip flow-export template options export-stats FS(config)# ip flow-export template options refresh-rate 35 FS(config)# ip flow-export template options timeout-rate 45</pre>
<b>Verification</b>	Run the <b>show ip flow export</b> command to display exported information.
	<pre>FS#showipflowexport IPV4 main Cache:   Exporting flows to 192.168.2.2(9996)   Exporting using source IP address 192.168.2.1   Version 0 flow records   IPV4 Template ID = 257     Template timeout = 30 Minute(s)     Template refresh rate = 40   0 flows exported in 0 udp datagrams   0 flows failed to export</pre>

### Common Errors

N/A

### 11.4.3 Configuring Parameters for the Main Mode Flow Table

#### Configuration Effect

- Adjust the aging time of flow records in the flow table.

#### Notes

- If the IPFIX function is enabled globally (the **{ ip } flow ingress** or **{ ip } flow egress** command is configured on a port), the change on the maximum number of entries that can be cached does not take effect immediately unless the IPFIX function is enabled globally again or the device is restarted. On any port with the IPFIX function enabled, you can run the **no { ip } flow ingress** or **no { ip } flow egress** command to disable the IPFIX function on all ports so as to disable the IPFIX function globally. Then, run the **{ ip } flow ingress** command to enable the IPFIX flow statistics again.

#### Configuration Steps

##### 📄 Configuring the Aging Time of Flow Records

- Optional.
- Run the **ip flow-cache timeout { active *minutes* | inactive *seconds* }** command to modify the inactive aging time and active aging time.
- When traffic needs to be displayed on the server in real time, it is recommended to set the aging time to a smaller value, for example, set the active aging time to 1 minute.

- Modifying aging time affects how long a flow record is stored in the flow table. If the aging time is set to a larger value, flow records exist in the flow table longer and the IPFIX server is slower in receiving the flow records.

<b>Command</b>	<b>{ ip   ipv6 } flow-cache timeout { active <i>minutes</i>   inactive <i>seconds</i> }</b>
<b>Parameter Description</b>	<b>active <i>minutes</i></b> : Indicates the active aging time, in minutes, that is, the time that an active entry can exist in the main mode cache before export or deletion. The valid value range is from 1 to 60 and the default value is 30. <b>inactive <i>seconds</i></b> : Indicates the inactive aging time, in which no flow record about an entry is detected before the main mode entry is aged. The value ranges from 10 seconds to 600 seconds. The default value is 15 seconds.
<b>Defaults</b>	The default inactive aging time is 15 seconds and the default active aging time is 30 minutes.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### Verification

- Run the **show { ip | ipv6 } flow cache** command to display information about the main mode flow table.

### Configuration Example

#### ▾ Configuring Parameters for the Main Mode Flow Table

<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Configure the active aging time for flow records.</li> <li>● Configure the inactive aging time for flow records.</li> </ul>
	<pre>FS# config terminal FS(config)# ip flow-cache timeout active 2 FS(config)# ip flow-cache timeout inactive 20</pre>
<b>Verification</b>	Run the <b>show ip flow cache</b> command to display information about the main mode flow table.
	<pre>FS# show ip flow cache</pre>

### Common Errors

## Data Center Configuration

1. Configuring DCB
2. Configuring VXLAN

# 1 Configuring DCB

## 1.1 Overview

A data center (DC) mainly processes the following three traffic types:

- Storage traffic: The requirement of packet integrity must be met.
- High-performance computing traffic: The requirement of low delay must be met.
- Ethernet traffic: Certain degree of packet loss and delay are allowed.

Due to the different requirements for the three traffic types, traditional DC bears the traffic on three types of networks, as shown in Figure 1-1.

Figure 1-1 Three types of DC networks

This topology configuration is feasible for a small-sized DC. If the DC grows, running the three types of networks becomes costly. An alternative method is to bear the three traffic types on Ethernet and define additional mechanisms, so that the Ethernet can meet the requirements of the three types of networks. The following definitions are formulated in IEEE to implement the method:

- Priority-based Flow Control (PFC): a mechanism that avoids packet loss in storage traffic and impact on other traffic types if the three traffic types coexist on Ethernet.
- Data Center Bridging Capability Exchange Protocol (DCBX): a protocol that is defined by IEEE 802.1Qaz for negotiating the data center bridge (DCB) capability. With the Link Layer Discovery Protocol (LLDP), DCBX discovers devices and exchanges DCB capability.

## Protocols and Standards

- IEEE Std 802.1Qaz
- IEEE 802.1Qbb
- IEEE 802.1Qau
- IEEE 802.3bd

## 1.2 Applications

Application	Description
Configuring DC Network	The Ethernet of a DC bears three types of data traffic.

### 1.2.1 Configuring DC Network

#### Scenario

The DC Ethernet bearing three types of data traffic must meet the following requirements:

- Storage traffic: The requirement of packet integrity must be met.
- High-performance computing traffic: The requirement of low delay must be met.
- Ethernet traffic: Certain degree of packet loss and delay are allowed.

Figure 1-2

#### Deployment

- Enable PFC for storage traffic to meet the requirement of packet integrity.
- Map the packet priority of high-performance computing traffic to the traffic class (TC) which boasts strict priority (SP) algorithm.
- Allocate bandwidth to the TC of Ethernet traffic.

## 1.3 Features

### Basic Concepts

#### ↘ 802.1p (Cos)

In 802.1p, the L2 header Virtual Local Area Network (VLAN) tag field falls into 8 priorities, ranging from 0 to 7.

16bit	3 bi t		12bit
Tag Protocol ID (0x8100)	pr io rit y		VLAN ID

Traffic with priorities in the range 0~2 indicates common Ethernet traffic that is transmitted with maximum capability; traffic with priority 3 indicates Fiber Channel Over Ethernet (FCoE) Storage Area Network (SAN) traffic; traffic with priorities 4 and 5 indicates delay-sensitive voice traffic; and traffic with priorities 6 and 7 indicates delay-sensitive main traffic. Traffic with priority 7 indicates network control packets.

#### ↘ Trust edge and application priority identification

By default, Ethernet ports are untrusted ports and need to be set to trust mode, so that packets carrying 802.1p value tags can be mapped to corresponding TC. The priority of untagged packets is 0 by default and can be modified.

The identified priority of FCoE packets is 3 by default and can be modified. The priority identification function must be enabled on a network interface card (NIC) which supports DCBX. If the NIC does not support DCBX, the priority identification function will be ignored.

If NICs do not support DCBX or users require more detailed priority identification function, configure Quality of Service (QoS) policies on ports to map an access control list (ACL) and identify application priority; or modify the FCoE packet priority on the servers directly connected to switches.

#### ↘ Queue and TC

A switch port has 3~8 queues for caching packets. A traffic class (TC) can be a single queue caching packets with different priorities or composed of multiple queues, with each queue caching packets of specified priority. The SP algorithm can be performed for a TC.

For example, TC 1 contains queue 1 only, and queue 1 caches packets with priorities 0~2; or TC 1 contains queues 0~2, where, queue 0 caches packets with priority 0, queue 1 caches packets with priority 1, and queue 2 caches packets with priority 2. Meanwhile, the SP algorithm may be enabled for queues 0~2 to ensure that packets with priority 2 are transmitted first.

#### ↘ Mapping list

Packets are mapped to a TC in the mapping list according to identified priority and then allocated to a specific queue of the TC.

- A TC is composed of multiple queues.

Each packet with a priority is mapped to a specific queue of the TC. The following table lists the mapping relationship between priorities and queues.

<b>Cos</b>	0	1	2	3	4	5	6	7
<b>Queue</b>	0	1	2	3	4	5	6	7

Queues in a TC are associated with the priorities mapped. According to the mapping list, users can modify queues contained in a TC. For example, users can map priorities 0~2 to TC 1, then TC 1 contains queues 0~2 that are associative with priorities 0~2.

- A TC contains a single queue.

A TC is associative with a specific queue. The following table lists the mapping relationship between queues and TCs.

<b>Queue</b>	0	1	2	3	4	5	6	7
<b>TC</b>	0	1	2	3	4	5	6	7

According to the mapping list, the mapping relationship between priorities and TCs is the mapping relationship between priorities and queues. For example, if priority 3 is mapped to TC 1, packets with priority 3 will be mapping to queue 1 of TC 1.

**Overview**

Feature	Description
PFC	Implements PFC on packets based on 802.1p value. If traffic of specified priority becomes congested, stops forwarding packets of this priority and instructs the transmitting device to stop sending such packets. With this function, packet integrity of Ethernet can be ensured.
DCBX	The DCBX device on the edge access layer instructs the servers connected to automatically synchronize with the DCBX device.

**1.3.1 Configuring PFC**

With PFC, packet integrity of the storage traffic can be ensured and impact on other traffic types can be avoided if the three traffic types, storage traffic, high-performance computing traffic, and Ethernet traffic, coexists on Ethernet. An 802.1p value is allocated to the storage traffic, and the PFC function is enabled for the priority. Other 802.1p values are allocated to the high-performance computing traffic and Ethernet traffic and the PFC function is disabled.

**Working Principle**

PFC is an enhanced version of the flow control function. Generally, if a receiver is unable to process received packets, the receiver instructs the packet sender to stop sending packets, which avoids packet loss. The flow control function is implemented by receiving or sending PAUSE frames via ports.

Figure 1-3 Flow control

As shown in Figure 1-3, when ports Gi 0/1 and Gi 0/2 forward packets at 1 Gbps, port Fa 0/1 will be congested. To avoid packet loss, enable the flow control function on ports Gi 0/1 and Gi 0/2.

- If port Fa 0/1 is congested in the course of forwarding packets, switch B will cache the packets. When the traffic exceeds the forwarding capability of switch B, packets will be lost. In this case, port Gi 0/2 will send a PAUSE frame to port Gi 0/1, instructing port Gi 0/1 to stop forwarding packets.

- Upon receiving the PAUSE frame, port Gi 0/1 stops forwarding packets to port Gi 0/2. The pause time is subject to the information carried in the PAUSE frame. If the congestion problem persists after the pause time is up, the preceding procedure will repeat until the congestion problem is cleared.

As described above, the flow control function can avoid packet loss, but it will result in link stop as well. That is, the entire link is stopped. The PFC function, however, allows eight virtual links to be created over an Ethernet link and specifies an 802.1p value for each virtual link. Any virtual link can be paused or restarted independently, without causing traffic interruption to other virtual links.

Figure 1-4 PFC

As shown in the preceding figure, enable the PFC function on ports Gi 0/1 and Gi 0/2 for priority 3.

- If port Fa 0/1 is congested in the course of forwarding packets with priority 3, switch B will cache the packets. When the traffic exceeds the forwarding capability of switch B, port Gi 0/2 will send a PFC PAUSE frame to port Gi 0/1, instructing port Gi 0/1 to stop forwarding packets with 802.1p value 3.
- Upon receiving the PFC PAUSE frame, port Gi 0/1 stops forwarding packets to port Gi 0/2. The pause time is subject to the information carried in the PFC PAUSE frame. If the congestion problem persists after the pause time is up, the preceding procedure will repeat until the congestion problem is cleared. As shown in the preceding figure, stopping forwarding packets with priority 3 will not have impact on packet transmission of other links between Gi 0/1 and Gi 0/2.

### Related Configuration

#### ▾ Enabling the PFC Function

The PFC function is disabled for any priority by default.

Run the **priority-flow-control nodrop cos-value-list {off | on}** command to enable the PFC function for a specified priority. *cos-value-list* indicates a priority list (range: 0~7); **on** indicates that the PFC function is enabled; and **off** indicates that the PFC function is disabled.

#### ▾ Disabling the PFC RX/TX Function

The PFC RX/TX function is enabled on the device by default.

Run the **priority-flow-control {rx | tx} disable** command to disable the PFC RX/TX function. After this command is configured, PFC PAUSE frames are not received or transmitted.

#### ▾ Configuring the Value of XOFF-TIME in a PFC Frame

By default, the value of **XOFF-TIME** in PFC frames sent by the device is **65535**.

Run the **priority-flow-control xoff-time** *number* command to configure the value of **XOFF-TIME** in PFC frames to be sent. The value of **XOFF-TIME** ranges from 1 to 65535. The unit of **XOFF-TIME** is the time required by the chip to send 512-bit data at the physical layer.

### ↘ Configuring Flow Rate Warning for Pause Frames for a Priority of an Interface

By default, no warning is generated when a device interface sends or receives Pause frames.

Run the **priority-flow-control early-warning** *cos-value-list* {**output pps rate-num** || **input pps rate-num**} command to configure the flow rate warning thresholds for Pause frames in the input and output directions for a specified PFC priority of an interface. *cos-value-list* indicates the configured priority list, and a priority ranges from 0 to 7. **output pps rate-num** indicates the threshold of Pause frames in the output direction while **input pps rate-num** indicates the threshold of Pause frames in the input direction.

If the rate for an interface at a specified priority to send/receive Pause frames exceeds the configured threshold (packets per second), a warning is generated and logged.

## 1.3.1.1 PFC Deadlock Detection

After the PFC priority is configured on the switch, the Ethernet is apt to encounter deadlock if a link is congested. This is called PFC deadlock.

### Working Principle

The figure below shows a typical scenario, in which devices in a data center have cyclic buffer areas that are mutually dependent. In the ring topology, any device may affect the buffer areas of the uplink device, and wait for its downlink device to release some buffer areas to recover the data packet transmission (dependency relationship). When Device A, Device B, and Device C reach the XOFF waterline and transmit PFC frames to the peer device at the same time, all switches in the topology are in the flow pause state, that is, deadlock occurs. The throughput of the entire network or part of the network becomes zero due to the back pressure effect of PFC Pause frames. A lot of facts show that deadlock surely occurs in such networks. Deadlock may also occur when a transient loop forms in a closed-loop network. In a data center, when a link fault occurs, a transient loop arises during the rerouting of the Border Gateway Protocol (BGP, an autonomous system routing protocol running over TCP); a transient loop may also appear during the update of the SDN-based data center. Though the transient loop disappears rapidly, the deadlock incurred persists. The system cannot automatically clear deadlock even after the error cause (for example, configuration error or link fault/update) is eliminated.

Figure 1- 5 Deadlock Principle

<b>Remarks</b>	Device A, Device B, and Device C are switches.
----------------	--

A buffer time can be set for PFC priority queues of a device interface to eliminate the deadlock. When a queue is congested and PFC Pause frames are received, a few time slices are still allocated for packet processing, to recover from the deadlock state.

When it is detected that an interface of a PFC priority enters the deadlock state frequently, the PFC function of the priority can be disabled to avoid impact on the normal forwarding of packets.

### Related Configuration

#### ▾ Configuring the PFC Deadlock Detection Time and Packet Processing Time for a Specified Priority

Run the **priority-flow-control deadlock cos-value *cos-value-list* [detect *detect-time* recover *recover-time* [continue | backoff *most-times*]]** command to configure the PFC deadlock detection time and packet processing time for a specified priority. (If the PFC deadlock detection time and packet processing time are not configured, default values are used.) **continue** indicates that an algorithm is enabled, in which an interface is always in the deadlock state and exits the deadlock state only when it does not receive PFC PAUSE frames. **backoff *most-times*** indicates that the recover-time backoff algorithm is enabled and *most-times* indicates the maximum number of backoff times. If **continue** or **backoff** is not configured, the recover-time algorithm is not enabled. After the deadlock recover-time ends, the interface directly exits the deadlock state.

#### ▾ Enabling the PFC Deadlock Detection Function for a Priority of an Interface

The PFC deadlock detection function is disabled for all priorities of all interfaces by default.

When the **priority-flow-control deadlock cos-value detect recover** command is executed to configure the global PFC deadlock detection function for a priority, you can run the **priority-flow-control deadlock cos-value *cos-value-list* enable** command to enable the PFC deadlock detection function for the specified priority of an interface.

After the PFC deadlock detection function is enabled for a specified priority of an interface, the interface will detect PFC deadlock events at this priority of the interface. If a PFC deadlock event occurs, the interface processes packets according to the configured policy. The **priority-flow-control deadlock drop** command is used to discard packets; if this command is not configured, packets are allowed to pass.

#### ▾ Configuring the PFC Deadlock Threshold Function

The PFC deadlock threshold function is disabled for all priorities by default.

After the **priority-flow-control deadlock cos-value detect recover** command is executed to configure the global PFC deadlock detection function for a priority, you can run the **priority-flow-control deadlock limit cos-value *cos-value-list* enable** command to enable the PFC deadlock threshold function for the specified priority.

After the PFC deadlock threshold function is enabled for a priority, if the number of deadlock times occurring for the priority within a detection period (1 minute by default) reaches the threshold (10 times by default), the PFC function is disabled for the priority, and the event and the disabling of the PFC function are logged (you can run the **show priority-flow-control deadlock status** command to display the logs).

## 1.3.2 Configuring DCBX

### Working Principle

#### ▾ DCBX version

Currently, market products support the following DCBX versions:

- CIN-DCBX: indicates the first-generation of DCBX designed by Cisco, Intel, and Nuova that is compatible with the converged network adapter (CNA).
- CEE-DCBX: indicates the second-generation of DCBX that is compatible with the CAN.
- IEEE-DCBX: indicates a standard DCBX that is defined by IEEE 802.1Qaz.

#### ↘ Negotiating DCB capability

DCBX encapsulates each DCB capability into an LLDP type/length/value (TLV). Based on the LLDP TLV, peer devices discover the DCB capabilities of neighboring devices and then negotiate with the neighboring devices according to the discovered DCB capabilities. By the negotiation, DCB configuration can be synchronized and error detection can be implemented at both ends.

DCB capabilities that need to be negotiated include PFC, and APP. The Willing field is contained in corresponding TLV of the capabilities. When the Willing field is 1, peer DCB configuration is acceptable; when the Willing field is 0, peer DCB configuration is unacceptable. DCB capabilities are negotiated based on the Willing field. The following table lists the values of the Willing field at both ends and negotiation results.

Local Willing Field	Peer Willing Field	Negotiation Result
1	1	DCB configuration of the device with smaller media access control (MAC) address is selected as a common DCB configuration.
1	0	Peer DCB configuration is selected.
0	1	Local DCB configuration is selected.
0	0	If DCB configuration at both ends is the same, negotiation succeeds; otherwise, negotiation fails.

#### Related Configuration

The DCBX function is enabled by default, so DCB capability configuration can be performed without additional configuration.

### 1.4 Configuration

Configuration	Description and Command
Configuring Basic Functions of the PFC	 (Mandatory) It is used to enable the PFC capability.
	<b>priority-flow-control nodrop</b> <i>cos-value-list</i> { <b>off</b>   <b>on</b> } <span style="float: right;">Configures the PFC function for specified priorities.</span>
	<b>priority-flow-control {rx   tx} disable</b> <span style="float: right;">Disables the PFC RX/TX function.</span>
	<b>priority-flow-control xoff-time</b> <i>number</i> <span style="float: right;">Configures the value of <b>XOFF-TIME</b> in a PFC frame.</span>
	<b>priority-flow-control early-warning</b> <i>cos-value-list</i> { <b>output</b> <b>pps</b> <i>rate-num</i> ]   <b>input</b> <b>pps</b> <i>rate-num</i> } <span style="float: right;">Configures the flow rate warning for a priority of an interface.</span>
	<b>priority-flow-control counting-interval</b> <i>number</i> <span style="float: right;">Configures the global PFC statistics collection interval.</span>
	<b>priority-flow-control deadlock</b> <i>cos-value</i> <i>cos-value-list</i> [ <b>detect</b> <i>detect-time</i> <b>recover</b> <i>recover-time</i> [ <b>continue</b>   <b>backoff</b> <i>most-times</i> ] ] <span style="float: right;">Configures attributes of the PFC deadlock detection function for a PFC priority.</span>
	<b>priority-flow-control deadlock</b> <i>cos-value</i> <i>cos-value-list</i> <b>enable</b> <span style="float: right;">Enables the PFC deadlock detection function for a priority of an interface.</span>

	<b>priority-flow-control deadlock drop</b>	Configures the function of discarding packets in the PFC deadlock state.
	<b>priority-flow-control deadlock precision low</b>	Sets the PFC deadlock time precision to <b>low</b> .
	<b>priority-flow-control deadlock limit frequency</b> <i>number</i> { <b>period</b>   <b>period-second</b> } <i>time</i>	Configures the PFC deadlock threshold and detection period.
	<b>priority-flow-control deadlock limit cos-value</b> <i>cos-value-list</i> <b>enable</b> [ <b>rx</b> ]	Enables the PFC deadlock threshold function for a priority.
Configuring Basic Functions of the DCBX	 (Mandatory) It is used to discover, detect, and negotiate peer DCB capabilities.	
	<b>dcbx enable</b>	Enables the global and interface DCBX function.
	<b>dcbx mode</b> { <b>auto</b>   <b>cee</b>   <b>ieee</b> }	Configures the DCBX mode of interfaces.
	<b>dcbx</b> { <b>pfc</b>   <b>app-proto</b> } <b>advertise</b>	Configures the DCBX TLV type that can be released on ports.
	<b>dcbx</b> { <b>pfc</b>   <b>app-proto</b> } <b>willing enable</b>	Enables DCB capability synchronization for ports.

- Remark: Configuration commands vary with specific products. For details about the commands, refer to DCB Commands.

#### 1.4.1 Configuring Basic Functions of the PFC

##### Configuration Effect

- Implement PFC for port data traffic based on 802.1p values.

##### Notes

- PFC is applicable to point-to-point (P2P) full-duplex links only.
- The PFC function conflicts with ordinary flow control function.
- If the priorities with PFC enabled and the priorities with PFC disabled are mapped to a queue, packets with the latter priorities will be suppressed. Generally, it is not recommended to map such priorities to a same queue.
- The PFC function is not applicable to packets sent by a CPU.
- The PFC function can take effect after a port trusts the CoS values.
- Priorities with the PFC function enabled cannot be mapped to a TC or queue that contains any other priorities (including priorities with the PFC function enabled). In another word, priorities mapped to a TC or queue cannot have the PFC function enabled.

##### Configuration Steps

###### 📌 Enabling the PFC function

- The PFC function is disabled for packets with any priority by default. To implement PFC on specified priority, configure PFC.

##### Verification

- Check the display result.

##### Related Commands

### ▾ Enabling the PFC function

<b>Command</b>	<b>priority-flow-control nodrop <i>cos-value-list</i> {off   on}</b>
<b>Parameter Description</b>	<i>cos-value-list</i> : Indicates a priority list (range: 0~7). <b>on</b> : Enables the PFC function of a priority. <b>off</b> : Disables the PFC function of a priority.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

<b>Command</b>	<b>priority-flow-control nodrop <i>cos-value-list</i> {off   on}</b>
<b>Parameter Description</b>	<i>cos-value-list</i> : Indicates a priority list (range: 0~7). <b>on</b> : Enables the PFC function of a priority. <b>off</b> : Disables the PFC function of a priority.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	The PFC function can be automatically negotiated and configured based on DCBX. After the PFC function is configured on the CLI, configuration results fall into the following scenarios: 1) The PFC function is automatically negotiated and configured based on DCBX. The automatic configuration takes effect. 2) The PFC function is not automatically negotiated and configured based on DCBX. The configuration on the CLI takes effect.

### ▾ Disabling the PFC RX/TX Function

<b>Command</b>	<b>priority-flow-control { rx   tx } disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global or interface configuration mode
<b>Usage Guide</b>	(1) By default, the PFC RX/TX function is enabled. When this command is configured, the PFC function is disabled. (2) This command can be configured in global or interface configuration mode depending on the chip capability. When the PFC RX/TX function supports the global configuration capability, the command is unavailable on interfaces. (3) When the PFC RX/TX function supports the interface configuration capability, the command can be configured in global configuration mode and the configuration can be saved to each interface. The configuration is displayed only on interfaces.

### ▾ Configuring the Value of XOFF-TIME in a PFC Frame

<b>Command</b>	<b>priority-flow-control xoff-time <i>number</i></b>
<b>Parameter Description</b>	<i>number</i> : Indicates the value of <b>XOFF-TIME</b> in a PFC frame, ranging from 1 to 65535. (The unit of <b>XOFF-TIME</b> is the time required by the chip to send 512-bit data at the physical layer.)
<b>Command Mode</b>	Global or interface configuration mode

<b>Usage Guide</b>	(1) Use this command to configure the value of <b>XOFF-TIME</b> in a PFC frame. The default value of <b>XOFF-TIME</b> is <b>65535</b> .
	(2) This command can be configured in global or interface configuration mode depending on the chip capability. When the PFC frame XOFF-TIME function supports the global configuration capability, the command is unavailable on interfaces.
	(3) When the PFC frame XOFF-TIME function supports the interface configuration capability, the command can be configured in global configuration mode and the configuration can be saved to each interface. The configuration is displayed only on interfaces.

▾ **Configuring Flow Rate Warning for a Priority of an Interface**

<b>Command</b>	<code>priority-flow-control early-warning cos-value-list { output pps rate-num }   input pps rate-num}</code>
<b>Parameter</b>	<i>cos-value-list</i> : Indicates the configured priority list. The priority ranges from <b>0</b> to <b>7</b> .
<b>Description</b>	<i>rate-num</i> : Indicates the flow rate warning value. The value ranges from <b>1</b> to <b>148809523</b> .
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	N/A

▾ **Configuring the Global PFC Statistics Collection Interval**

<b>Command</b>	<code>priority-flow-control counting-interval number</code>
<b>Parameter</b>	<i>number</i> : Indicates the statistics collection interval in seconds. The value ranges from <b>1</b> to <b>20</b> .
<b>Description</b>	
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

**Configuration Example**

▾ **Enabling PFC for 802.1p value 3**

### Common Errors

- The common flow control function is not disabled. As a result, PFC fails to be enabled.
- A port is not set to trust the CoS values.
- Priorities with the PFC function enabled are mapped to a TC that contains any other priorities (including priorities with the PFC function enabled).

## 1.4.1.1 Configuring the PFC Deadlock Detection Function

### Configuration Effect

- If the PFC deadlock detection is enabled for a PFC priority on a port and deadlock is detected, allow packets to pass or discard packets within a period of time as per the configured policy.
- If the PFC deadlock threshold function is enabled for a PFC priority and it is detected that the number of deadlock times reaches the threshold, disable the PFC function of the PFC priority.

### Notes

- The prerequisite for the PFC deadlock detection function to take effect for a priority is that the PFC function must be enabled for the priority.
- The prerequisite for the PFC deadlock threshold function to take effect for a priority is that the PFC deadlock detection function is configured for the priority.
- Modifying PFC deadlock time precision will affect the detection time and packet processing time of the configured PFC deadlock detection function.

- Disabling the PFC deadlock detection function for a priority will delete the configuration of the PFC deadlock threshold function of the priority.
- Disabling the global PFC deadlock detection function or PFC function for a priority will delete the configuration of the PFC deadlock detection function for the priority on all interfaces.

**Configuration Steps**

▾ **Enabling the PFC Deadlock Detection Function**

- The PFC deadlock detection function is disabled for all priorities on all interfaces by default. Configure the global PFC deadlock detection function for a priority and set attribute parameters (use default parameter values if no parameter is configured), and then enable the PFC deadlock detection function for the relevant priority on a specified interface.

▾ **Enabling the PFC Deadlock Threshold Function**

- The PFC deadlock threshold function is disabled for all priorities by default. The PFC deadlock threshold function can be enabled for a priority, for which the PFC deadlock detection function has been enabled. The threshold can be globally configured.

**Verification**

▾ **Checking the Configuration of the PFC Deadlock Detection Function and Threshold Function**

- Run the **show priority-flow-control deadlock status** command to display the configuration of the PFC deadlock detection function and threshold function, and check whether the functions are enabled, configured parameter values, and the interfaces and priorities for which the PFC deadlock detection function is enabled.

<b>Command</b>	<b>show priority-flow-control deadlock status</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Privileged EXEC mode, global configuration mode, and interface configuration mode
<b>Usage Guide</b>	<p>Check the configuration and enabling status of the PFC deadlock function.</p> <pre> FS#show priority-flow-control deadlock status Global PFC Deadlock: 1-2 Time Precision: Low&lt;100ms&gt; Packet Dispose: Forward Limit Cos-value: off Limit Period: 5 Limit Frequency: 10 Priority Attribute: Cos-value Detect-time Recover-time ----- 1          1          10 2          15         20  Interface Enable: Interface  Cos-value -----  -----                     </pre>

Field description:			
Field	Description		
Global PFC Deadlock	Priority value configured for the PFC deadlock function		
Time Precision	PFC deadlock time precision. High precision (100ms) is configured by default.		
Packet Dispose	Packet processing mode in the PFC deadlock state. The value is <b>Forward</b> in the preceding example.		
Limit Cos-value	Priority value configured for the PFC deadlock threshold		
Limit Period	Detection period set for the PFC deadlock threshold		
Limit Frequency	PFC deadlock threshold		
Priority Attribute	PFC deadlock priority attributes (cos-value, detection time, and recovery time)		
Interface Enable	Interface on which the PFC deadlock function is enabled and priority information (interface name and enabling priority)		
Limit Log	PFC deadlock threshold log (recording the historical disabling of the PFC function resulted from that the number of PFC deadlock events exceeds the threshold)		
Interface	Interface on which the number of PFC deadlock events exceeds the threshold		
Cos-value	Priority for which the number of PFC deadlock events exceeds the threshold		
Frequency	Number of PFC deadlock events that occur in a period		
Time	Time at which the number of PFC deadlock events exceeds the threshold		

**Related Commands**

↘ **Configuring Attributes of the PFC Deadlock Detection Function for a PFC Priority**

<b>Command</b>	<code>priority-flow-control deadlock cos-value cos-value-list [detect detect-time recover recover-time [continue   backoff most-times] ]</code>
<b>Parameter Description</b>	<p><i>cos-value-list</i>: Indicates the priority list. The priority ranges from <b>0</b> to <b>7</b>.</p> <p><i>detect-time</i>: Indicates the deadlock detection time in time slices. The value ranges from <b>1</b> to <b>15</b>. The default value is <b>15</b>.</p> <p><i>recover-time</i>: Indicates the deadlock recovery time in milliseconds. The value ranges from <b>10</b> to <b>3000</b>. The default</p>

	<p>value is <b>150</b>.</p> <p><b>continue</b>: Indicates the continue algorithm used to calculate the deadlock recover-time.</p> <p><b>backoff most-times</b>: Indicates the backoff algorithm used to calculate the deadlock recover-time. <i>most-times</i> indicates the maximum number of backoff times. The value ranges from <b>2</b> to <b>100</b>.</p>
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>The PFC deadlock detection function detects whether an interface at a PFC priority enters the PFC deadlock state. When it is detected that the interface enters the PFC deadlock state, the interface forwards or discards received packets within a period of time. You can run the <b>priority-flow-control deadlock drop</b> command to configure the packet processing mode.</li> <li>You can use this command to configure attributes of the PFC deadlock detection function for PFC priorities.</li> <li><i>detect-time</i>: Indicates the time for determining whether an interface at a PFC priority enters the PFC deadlock state. When the interface stays in the PFC congested state in consecutive detect-time periods, it indicates that the interface enters the PFC deadlock state.</li> <li><i>recover-time</i>: Indicates the allowed packet processing time after an interface at a PFC priority enters the PFC deadlock state.</li> <li><i>detect-time</i> is in unit of time slice. You can run the <b>priority-flow-control deadlock precision low</b> command to configure the length of one time slice. <i>recover-time</i> is in unit of milliseconds.</li> <li><b>continue</b>: Indicates that an interface of the priority in the deadlock state continues in this state for one recover-time period if it receives PFC PAUSE frames. The interface checks whether it receives PFC PAUSE frames in the next recover-time period. If the interface still receives such frames, it continues to be in the deadlock state for another recover-time period. The process repeats till the interface does not receive PFC PAUSE frames within the recover-time period and then the interface exits the deadlock state.</li> <li><i>most-times</i>: indicates the maximum number of recover-time backoff times. If an interface enters the deadlock state within the backoff period (<math>\text{recover-time} \times \text{most-times}</math>) after it recovers from the first deadlock, the backoff time needs to be added to the recover-time (<math>\text{Backoff time} = \text{Number of backoff times} \times \text{recover-time}</math>). If the interval between two deadlock states exceeds the backoff period, the number of backoff times is reset to zero. Otherwise, the number of backoff times increases by 1 (if the number of backoff times already reaches the maximum number of backoff times, the maximum number of backoff times, that is, <i>most-times</i>, is used.)</li> <li>If neither <b>continue</b> nor <b>backoff</b> is configured, the deadlock recover-time algorithm is disabled. After the deadlock recover-time ends, the interface directly exits the deadlock state.</li> </ol>

#### 📌 Enabling the PFC Deadlock Detection Function for a Priority of an Interface

<b>Command</b>	<b>priority-flow-control deadlock cos-value <i>cos-value-list</i> enable</b>
<b>Parameter Description</b>	<i>cos-value-list</i> : Indicates the configured priority list. The priority ranges from <b>0</b> to <b>7</b> .
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>When the <b>priority-flow-control deadlock cos-value detect recover</b> command is not executed to globally configure the PFC deadlock detection function for a priority, the PFC deadlock detection function cannot be enabled on interfaces for the priority.</li> <li>Likewise, if the <b>priority-flow-control deadlock cos-value detect recover</b> command, the PFC deadlock detection function will be disabled on all interfaces for the priority.</li> </ol>

#### 📌 Configuring the Function of Discarding Packets in the PFC Deadlock State

<b>Command</b>	<b>priority-flow-control deadlock drop</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<p>If this command is not configured, an interface at a PFC priority forwards packets after entering the PFC deadlock state.</p> <p>If this command is configured, an interface at a PFC priority discards packets after entering the PFC deadlock state.</p>

#### ▾ Setting the PFC Deadlock Time Precision to Low

<b>Command</b>	<b>priority-flow-control deadlock precision low</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. This command is used to configure the length of a single deadlock time slice. It affects the detect time unit in the <b>priority-flow-control deadlock cos-value cos-value-list detect detect-time recover recover-time</b> command.</li> <li>2. When this command is not configured, the PFC deadlock time precision is high (one time slice equals 10ms). After this command is configured, the PFC deadlock time precision is low (one time slice equals 100ms).</li> <li>3. After the PFC deadlock function is configured for a priority, configuring this command will modify the time precision of the PFC deadlock function for the priority.</li> </ol>

#### ▾ Enabling the PFC Deadlock Threshold Function for a Priority

<b>Command</b>	<b>priority-flow-control deadlock limit cos-value cos-value-list enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. This command is not configured by default. Configuring this command will enable the PFC deadlock threshold function for the PFC priority corresponding to <i>cos-value-list</i>. If the number of deadlock times occurring for a priority within one detection period (1 minute by default) reaches the threshold (10 times by default), the PFC function is disabled for the priority via the <b>priority-flow-control nodrop cos-value-list off</b> command.</li> <li>2. This command relies on the configuration of the <b>priority-flow-control deadlock cos-value cos-value-list detect detect-time recover recover-time</b> command. This command can be configured only after the command for configuring attributes of the PFC deadlock detection function is configured for a priority. Likewise, if the command for configuring attributes of the PFC deadlock detection function is deleted for a priority, the PFC deadlock threshold command of the priority is also deleted.</li> <li>3. You can run the <b>priority-flow-control deadlock limit frequency number period time</b> command to configure the detection period and deadlock threshold.</li> </ol>

#### ▾ Configuring the PFC Deadlock Threshold and Detection Period

<b>Command</b>	<b>priority-flow-control deadlock limit frequency number period time</b>
<b>Parameter Description</b>	N/A

<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This command modifies the PFC deadlock threshold and detection period. When the <b>priority-flow-control deadlock limit cos-value cos-value-list enable</b> command is executed to enable the PFC deadlock threshold function for a PFC priority, the PFC deadlock threshold and detection period configured using this command are applied.

**Configuration Example**

➤ **Enabling the PFC Deadlock Detection Function and Deadlock Threshold Function for Priority 3**

<p><b>Scenario</b> Figure 1-7</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Set PFC IEEE 802.1p priority to 3 on the server.</li> <li>● Enable the PFC function for Priority 3 on the switch.</li> </ul>
<p><b>A</b></p>	<pre>FS(config)# priority-flow-control nodrop 3 on</pre> <ul style="list-style-type: none"> <li>● Set attributes of the PFC deadlock detection function for Priority 3 on the switch: Set the detection time to 5 time slices, recovery time to 20ms, and time precision to low.</li> </ul> <pre>FS(config)# priority-flow-control deadlock cos-value 3 detect 5 recover 20 FS(config)# priority-flow-control deadlock precision low</pre> <ul style="list-style-type: none"> <li>● Enable the PFC deadlock detection function for Priority 3 on Interface Hu0/1 of the switch.</li> </ul> <pre>FS(config)#interface hundredGigabitEthernet 0/1 FS(config-if-HundredGigabitEthernet 0/1)#priority-flow-control deadlock cos-value 3 enable</pre> <ul style="list-style-type: none"> <li>● Enable the PFC deadlock threshold function for Priority 3, set the detection time to 5 minutes, and threshold to 100 times.</li> </ul> <pre>FS(config-if-HundredGigabitEthernet 0/1)#exit FS(config)#priority-flow-control deadlock limit frequency 100 period 5 FS(config)# priority-flow-control deadlock limit cos-value 3 enable</pre>
<p><b>Verification</b></p>	<p>Check the displayed configuration.</p>
<p><b>A</b></p>	<pre>FS# show priority-flow-control deadlock status Global PFC Deadlock: 3 Time precision: Low&lt;100ms&gt; Packet dispose: Forward Limit cos-value: 3 Limit period: 5 Limit frequency: 100 Priority attribute: cos-value detect-time recover-time ----- 3          5          20  Interface Enable:</pre>

-----	-----

### Common Errors

- The PFC deadlock detection function is enabled on an interface without globally configuring the PFC deadlock detection function for a priority or globally enabling the PFC function for a priority in advance.
- The PFC deadlock threshold function is configured without globally configuring attributes of the PFC deadlock detection function for a priority.

### 1.4.2 Configuring Basic Functions of the DCBX

#### Configuration Effect

- Discover peer DCB capabilities.
- Check whether DCB capabilities configured for both ends are the same.
- Automatically negotiate and configure DCB.

#### Notes

- The DCB capability negotiation function can take effect on interfaces only after the following requirements are met: the LLDP function is enabled in global configuration mode and interface configuration mode; the LLDP working mode of the interfaces is set to txrx; the TLV of corresponding DCB capability can be released; and corresponding DCB capability is supported. If the requirements are not met, the DCBX function will not take effect even if it is enabled on the interfaces.
- When configuring AP ports, make sure that the LLDP of different AP member ports is set to the same value, the AP port topology is correctly set, and the DCBX TLV released for different AP member ports is the same. Otherwise, abnormalities occur when DCB capabilities are negotiated on the AP ports at both ends.

#### Configuration Steps

##### ▾ Enabling DCBX

- The global and interface DCBX function is enabled by default.
- Enable DCBX in global or interface configuration mode to launch the DCB capability negotiation of the interface. Disabling the global DCBX function will disable the DCB capability negotiation of all interfaces. The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

##### ▾ Configuring a DCBX mode

- (Mandatory) Interfaces work in the automatic switch mode by default.
- (Interface configuration mode) The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

### ✚ Configuring DCBX TLV types that can be released

- (Mandatory) All types of DCBX TLV can be released on interfaces by default.
- (Interface configuration mode) The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

### ✚ Configuring synchronization willingness

- Local end is unwilling to receive peer configuration by default. That is, the Willing parameter is not set.
- During negotiation of DCB capability synchronization, specify the Willing parameter for local ports to receive peer configuration. If local end is willing to receive peer configuration, configure the Willing parameter.

#### Verification

- Check the display result.

#### Related Commands

### ✚ Enabling DCBX

<b>Command</b>	<b>dcbx enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command mode</b>	Global configuration mode/Interface configuration mode
<b>Usage Guide</b>	Disabling the global DCBX function will disable the DCB capability negotiation of all interfaces. AP ports negotiate DCB capabilities based on AP member ports.

### ✚ Configuring a DCBX mode

<b>Command</b>	<b>dcbx mode { auto   cee   ieee }</b>
<b>Parameter</b>	Interfaces work in the automatic switch mode by default.
<b>Description</b>	<p><b>auto</b>: Allows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in the automatic switch mode and the default mode is CEE-DCBX.</p> <p><b>cee</b>: Disallows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in CEE-DCBX mode.</p> <p><b>ieee</b>: Disallows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in IEEE-DCBX mode.</p>
<b>Command mode</b>	Interface configuration mode
<b>Usage Guide</b>	AP ports negotiate DCB capabilities based on AP member ports.

### ✚ Configuring DCBX TLV types that can be released

<b>Command</b>	<b>dcbx { pfc   app-proto } advertise</b>
<b>Parameter</b>	All types of DCBX TLV can be released on interfaces by default.
<b>Description</b>	<p><b>pfc</b>: Enables the DCBX TLV release function corresponding to the PFC capability.</p> <p><b>app-proto</b>: Enables the DCBX TLV release function corresponding to the APP capability.</p>
<b>Command mode</b>	Interface configuration mode

<b>Usage Guide</b>	AP ports negotiate DCB capabilities based on AP member ports. Types of DCBX TLV that can be released on AP ports will be applied to different AP member ports.
--------------------	---

▾ **Configuring synchronization willingness**

<b>Command</b>	<b>dcbx { pfc   app-proto } willing enable</b>
<b>Parameter</b>	<b>pfc</b> : Enables PFC capability synchronization willingness.
<b>Description</b>	<b>app-proto</b> : Enables APP capability synchronization willingness.
<b>Command mode</b>	Interface configuration mode
<b>Usage Guide</b>	AP ports negotiate DCB capabilities based on AP member ports. If the Willing parameter is set to the same value at both ends and the local and peer ports are willing to receive peer configuration, the configuration on the port with a smaller MAC address prevails. If the local and peer ports are unwilling to receive peer configuration, the same value of the Willing parameter indicates negotiation success; otherwise, it indicates negotiation failure. If DCB capabilities support only global configuration mode, they cannot be negotiated over DCBX. In this case, local configuration prevails. For example, if the PFC function supports only global configuration mode, even though the local PFC Willing bit is set to 1, the local port will not receive peer configuration. That is, the PFC capability cannot be negotiated, and local PFC configuration prevails.

**Configuration Example**

▾ **Automatically configuring DCB**

<b>Scenario</b> Figure 1-8	
<b>Configuration Steps</b>	<ul style="list-style-type: none"> <li>● Enable LLDP in global configuration mode and interface configuration mode (default configuration).</li> <li>● Set the LLDP mode of an interface to txrx (default configuration).</li> <li>● Enable DCBX of an interface (default configuration).</li> <li>● Allow all types of DCBX TLV to be released on an interface (default configuration).</li> </ul>
<b>A</b>	By default, switch A can instruct the server to automatically configure DCB, free users of manually configuring DCB.
<b>Verification</b>	Check the display result.
<b>A</b>	<pre>FS#show dcbx status interface GigabitEthernet 0/1 ----- Port [GigabitEthernet 0/1] -----  Local managing configuration information and port link state: PortstatusofDCBX                :Enable PortmodeofDCBX                   : AUTOmode PortactiveofDCBX                 : CEE active PFCisallowedtoadvertise          : Yes APPisallowedtoadvertise          : Yes PFCiswillingtoacceptpeerconfiguration : No</pre>

APP is willing to accept peer configuration	: No
Port link state	: UP
Negotiated configuration information:	
PFC negotiated result	: using local configuration
APP negotiated result	: using local configuration

### Common Errors

- The LLDP function is not enabled in global configuration mode or interface configuration mode.
- The LLDP mode of an interface is not set to txrx.

## 1.5 Monitoring

### Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistical information of PFC.	<b>clear priority-flow-control statistics</b> [ interface <i>interface-name</i> ]
Clears the PFC deadlock statistics of an interface	<b>clear priority-flow-control deadlock statistics</b> [interface <i>interface-name</i> ]

### Displaying

Description	Command
Displays global PFC configuration information.	<b>show priority-flow-control status</b>
Displays PFC configuration and status information of a port.	<b>show priority-flow-control status</b> [ interface <i>interface-name</i> ]
Displays statistical information of PFC.	<b>show priority-flow-control statistics</b> [interface <i>interface-name</i> ]
Displays the PFC deadlock statistics of all priorities of an interface.	<b>show priority-flow-control deadlock statistics</b> [interface <i>interface-name</i> ]
Displays PFC deadlock configuration and enabling status.	<b>show priority-flow-control status</b>
Displays DCBX configuration information and negotiation status of an interface.	<b>show dcbx status</b> [ interface <i>interface-name</i> ]
Displays DCB configuration information and capability negotiation status at both ends.	<b>show dcbx information</b> { pfc   app-proto } [ interface <i>interface-name</i> ]

### Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs the PFC deadlock function.	<b>debug pfc deadlock</b>
Debugs the PFC details.	<b>debug pfc detail</b>

Debugs the PFC error.	<b>debug pfc error</b>
Debugs the PFC event.	<b>debug pfc event</b>
Debugs the PFC statistics.	<b>debug pfc statistics</b>
Debugs ETS events.	<b>debug ets event</b>
Debugs DCBX events.	<b>debug dcbx event</b>
Debugs DCBX and DCB capability submodule interaction.	<b>debug dcbx detail</b>
Debugs error information during DCBX running.	<b>debug dcbx error</b>
Debugs packet transmission and receiving of DCBX.	<b>debug dcbx pkt</b>
Debugs change of the DCBX status machine.	<b>debug dcbx stm</b>
Debugs hotstandby information of DCBX.	<b>debug dcbx ha</b>
Debugs the DCB library.	<b>debug dcb-lib</b>

## 2 Configuring VXLAN

### 2.1 Overview

Virtual Extensible Local Area Network (VXLAN) is a virtual Ethernet based on the physical IP (overlay) network. It is a technology that encapsulates layer 2 (L2) Ethernet frames within layer 3 User Datagram Protocol (UDP) packets.

VXLAN has a 24-bit VXLAN network identifier (VNI). It allows users to create up to 16,000,000 isolated virtual networks to meet the requirements of multi-tenant environments and scale expansion, far surpassing the widely used Virtual Local Area Network (VLAN) technology that is limited to 4,000 isolated networks. VXLAN uses the IP multicast method to encapsulate multicast, broadcast, and unknown unicast packets, effectively controlling the broadcast domain in multi-tenant environments.

With the transformation of data centers, more and more virtual machines are deployed. In addition, as virtual machines must be migrated in L2 environments, scales of L2 networks increase. VXLAN can extend L2 networks over layer 3 (L3) networks, so that virtual machines can be moved to L3 networks interconnected to L2 networks without changing the IP addresses and MAC addresses, thereby ensuring service continuity.

#### Protocols and Standards

- RFC7348: Virtual eXtensible Local Area Network (VXLAN) -- A Framework for Overlaying Virtualized Layer 2 Networks over Layer 3 Networks

### 2.2 Applications

Application	Description
EVPN-based Multi-tenant Centralized Deployment	Applicable to the centralized deployment scenario with Ethernet virtual private network (EVPN) enabled.
EVPN-based Multi-tenant Distributed Deployment	Applicable to the distributed deployment scenario with EVPN enabled.
EVPN-based Single-tenant VXLAN Routing Deployment	Applicable to the VXLAN routing deployment scenario with a single tenant.

EVPN-based Multi-tenant VXLAN Route Deployment	Applicable to the VXLAN route deployment scenario with multiple tenants.
SDN Controller-based Centralized All-active Anycast Gateway Deployment	Applicable to the scenario for deploying all-active anycast gateways based on the software-defined networking (SDN) controller in a centralized manner data centers.
Deployment of an EVPN Distributed Network to Be Compatible with Non-EVPN VTEP Devices	Applicable to the deployment scenario in which dynamic and static tunnels coexist.
Deployment of L2 Subinterfaces to Access a VXLAN	Applicable to the deployment scenario in which hosts access VXLANs through L2 subinterfaces.
VNI Mapping-based Data Center Interconnection Deployment	Applicable to the scenario in which VXLANs across different data centers are interconnected using the VNI mapping technology.

## 2.2.1 EVPN-based Multi-tenant Centralized Deployment

### Scenario

VPN routing and forwarding (VRF) networks are usually allocated to different tenants to support the multi-tenant application in a data center. Multiple VXLANs can be assigned to each tenant. VXLANs of the same tenant can be mutually accessed through the L3 router, while VXLANs of different tenants cannot be mutually accessed, as shown in Figure 2-1.

Tenant A rents VRF-10, which includes VXLAN 10 and VXLAN 20. Servers HOST-1 and HOST-2 belong to VXLAN 10 and Servers HOST-3 and HOST-4 belong to VXLAN 20.

Tenant B rents VRF-20, which includes VXLAN 100. Servers HOST-5 and HOST-6 belong to VXLAN 100.

The networks of Tenant A and Tenant B are isolated from each other.

The entire network is formed by a Border Gateway Protocol (BGP) network and includes CORE and TOR switches. The BGP neighbor relationship is formed between every two devices and the BGP-EVPN protocol family is supported. All VXLAN gateways on the network are deployed in the core switches in a centralized manner.

Figure 2- 1

- Packets between HOST-1 and HOST-2 are forwarded through TOR-1 at L2 within the VXLAN.
- Packets between HOST-3 and HOST-4 are forwarded through TOR-1 > CORE > TOR-2 at L2 within the VXLAN.
- Packets between HOST-5 and HOST-6 are forwarded through TOR-2 at L2 within the VXLAN.
- Packets between VXLAN 10 and VXLAN 20 are forwarded through TOR-1 > CORE > TOR-2 at L3 across the VXLANs.
- VRF-10 and VRF-20 cannot communicate with each other.

<b>Remarks:</b>	<p>CORE indicates a core switch that supports the VXLAN function.</p> <p>When centralized all-active anycast gateways are deployed, multiple core gateways exist and the VXLAN gateways deployed on the core gateways are the same.</p> <p>TOR1 and TOR2 are access switches that support the VXLAN function.</p> <p>HOST-1, HOST-2, HOST-3, HOST-4, HOST-5, and HOST-6 are servers in the data center.</p>
-----------------	---

**Deployment**

- Configure an Internet Protocol version 4 (IPv4) unicast routing protocol, for example, the Open Shortest Path First (OSPF) protocol, on the switches to ensure that unicast routes are reachable.
- Configure the BGP routing protocol (supporting EVPN) on the switches to establish neighbor relationships between each other.
- Deploy the VXLAN gateway on the core switches.
- Deploy the VXLAN bridge on the TOR switches.

**2.2.2 EVPN-based Multi-tenant Distributed Deployment**

**Scenario**

The EVPN-based multi-tenant distributed deployment applies to data center networks that support multiple tenants. The difference between this deployment and the EVPN-based multi-tenant centralized deployment described in section 2.2.1 lies in that: On the distributed deployment network, gateways are deployed on the TOR switches, as shown in Figure 2-2.

Tenant A rents VRF-10, which includes VXLAN 10 and VXLAN 20.

Tenant B rents VRF-20, which includes VXLAN 100.

The networks of Tenant A and Tenant B are isolated from each other.

The entire network is formed by a BGP network and includes CORE and TOR switches. The BGP neighbor relationship is formed between every two devices and the BGP-EVPN protocol family is supported.

VXLAN gateways are deployed on TOR switches on the network. Anycast gateways can be deployed so that the IP addresses and MAC addresses of all gateways on the network are kept consistent. In this way, the gateway configuration does not need to be modified no matter which TOR switch a virtual machine of a customer is migrated to.

VXLANs are unnecessarily deployed on the core switches.

ARP suppression can be configured on TOR switches to curb flooding of ARP packets, and the TOR switches respond to ARP requests from hosts as a proxy.

The ARP proxy function can be enabled on the TOR switches for all or some VXLANs. In this way, L2 traffic in VXLANs is isolated and server communication traffic in the same VXLAN is forwarded at L3 rather than at L2.

ND suppression can be configured on TOR switches to curb flooding of IPv6 ND protocol packets, and the TOR switches respond to IPv6 NS multicast packets from hosts as a proxy.

Figure 2- 2

- Packets between HOST-1 and HOST-4 are forwarded through TOR-1 > TOR-2 at L2 within the VXLAN.

- Packets between HOST-1 and HOST-2 are forwarded through TOR-1 at L3 across the VXLANs.
- Packets between HOST-1 and HOST-5 are forwarded through TOR-1 > TOR-2 at L3 across the VXLANs.
- VRF-10 and VRF-20 cannot communicate with each other.
- If the ARP proxy function is configured on VXLAN 10, packets between HOST-1 and HOST-4 are forwarded through TOR-1 > TOR-2 at L3 within the VXLAN.

<b>Remarks:</b>	<p>CORE indicates a core switch that supports the BGP-EVPN function.</p> <p>TOR1 and TOR2 are access switches that support the VXLAN function.</p> <p>HOST-1, HOST-2, HOST-3, HOST-4, HOST-5, and HOST-6 are servers in the data center.</p>
-----------------	--

#### Deployment

- Configure an IPv4 unicast routing protocol, for example, the OSPF protocol, on the switches to ensure that unicast routes are reachable.
- Configure the BGP routing protocol (supporting EVPN) on the switches to establish neighbor relationships between each other.
- Deploy the VXLAN bridge on the core switches if required.
- Deploy the VXLAN gateway on the TOR switches.
- (Optional) Deploy ARP suppression on the TOR switches.
- (Optional) Deploy ARP proxy on the TOR switches.
- (Optional) Deploy IPv6 ND suppression on the TOR switches.
- (Optional) Deploy the EVPN protocol packet control function on the TOR switches to reduce the traffic of EVPN packets.

### 2.2.3 EVPN-based Single-tenant VXLAN Routing Deployment

#### Scenario

Single-tenant VXLAN route deployment is shown in Figure 2-3.

In this scenario, only the VRF-10 is deployed, which includes VXLAN 10 and VXLAN 20.

The border devices are connected to the external network. These devices are deployed in VRF-10 (including VXLAN 90) and interconnect with the external network at L3 via the overlay router interface.

The entire network is formed by a BGP network and includes TOR and border devices. The BGP neighbor relationship is formed between every two devices (except between Border-1 and Border-2) and the BGP-EVPN protocol family is supported.

The TOR and border devices must use a symmetric VXLAN (VXLAN 100) for interconnection with each other. The border devices import network routes to the TOR switches through the symmetric VXLAN.

VXLAN gateways are deployed on TOR switches on the network. Anycast gateways can be deployed so that the IP addresses and MAC addresses of all gateways on the network are kept consistent. In this way, the gateway configuration does not need to be modified no matter which TOR switch a virtual machine of a customer is migrated to.

Figure 2-3

- Packets between HOST-1 and HOST-3 are forwarded through TOR-1 > TOR-2 at L2 within the VXLAN.
- Packets between HOST-1 and HOST-2 are forwarded through TOR-1 at L3 across the VXLANs.
- To access the external network, HOST-1 forwards packets to the border device through TOR-1 at L3 across the VXLANs, and then the border device forwards the packets to the external network at L3.

### Deployment

- Configure an IPv4 unicast routing protocol, for example, the OSPF protocol, on the switches to ensure that unicast routes are reachable.
- Configure the BGP routing protocol (supporting EVPN) on the switches to establish neighbor relationships between each other (except between the border devices).
- Deploy the VXLAN on the border devices for L3 interconnection with the external network.
- Deploy the VXLAN gateway on the TOR switches.

### 2.2.4 EVPN-based Multi-tenant VXLAN Route Deployment

#### Scenario

VRF networks are usually allocated to different tenants to support the multi-tenant application in a data center. Multiple VXLANs can be assigned to each tenant. VXLANs of the same tenant can be mutually accessed through the L3 router, while VXLANs of different tenants cannot be mutually accessed, as shown in Figure 2-4.

Tenant A rents VRF-10, which includes VXLAN 10 and VXLAN 20.

Tenant B rents VRF-20, which includes VXLAN 30.

The border devices are connected to the external network. These devices are deployed in VRF-30 (including VXLAN 90) and interconnect with the external network at L3 via the overlay router interface.

The networks of Tenant A and Tenant B are isolated from each other.

The entire network is formed by a BGP network and includes TOR and border devices. The BGP neighbor relationship is formed between every two devices (except between Border-1 and Border-2) and the BGP-EVPN protocol family is supported

The TOR and border devices must use a symmetric VXLAN (VXLAN 100 and VXLAN200) for interconnection with each other. The border devices import network routes to the TOR switches through the symmetric VXLAN.

VXLAN gateways are deployed on TOR switches on the network. Anycast gateways can be deployed so that the IP addresses and MAC addresses of all gateways on the network are kept consistent. In this way, the gateway configuration does not need to be modified no matter which TOR switch a virtual machine of a customer is migrated to.

Figure 2-4

- Packets between HOST-1 and HOST-4 are forwarded through TOR-1 > TOR-2 at L2 within the VXLAN.
- Packets between HOST-1 and HOST-2 are forwarded through TOR-1 at L3 across the VXLANs.
- To access the external network, HOST-1 forwards packets to the border device through TOR1 at L3 across the VXLANs, and then the border device forwards the packets to the external network at L3.

**Deployment**

- Configure an IPv4 unicast routing protocol, for example, the OSPF protocol, on the switches to ensure that unicast routes are reachable.
- Configure the BGP routing protocol (supporting EVPN) on the switches to establish neighbor relationships between each other (except between the border devices).
- Deploy the VXLAN on the border devices for L3 interconnection with the external network.

- Deploy the VXLAN gateway on the TOR switches.

## 2.2.5 SDN Controller–based Centralized All-active Anycast Gateway Deployment

### Scenario

SDN controller–based centralized all-active anycast gateway deployment applies to data center networks that support the control of an SDN controller, as shown in Figure 2-5.

#### 1. VXLAN overlay network topology:

In this scenario, the VXLAN overlay network is a two-layer structure including a core layer and an access layer.

- 1) TOR switches serve as VXLAN bridges to directly connect to servers (virtual machines).
- 2) Core switches serve as VXLAN gateways. Multiple all-active VXLAN physical gateways are deployed in a centralized manner. The physical gateways are in the all-active state. The anycast function is deployed on each physical gateway and the same IP address and MAC address are configured on all gateways to form a logical gateway. The fault of any particular physical gateway does not affect the normal operation of the logical gateway.
- 3) Virtual tunnel end points (VTEPs), including VXLAN bridges and VXLAN gateways, interconnect with each other through the L3 underlay network.
- 4) At the underlay layer, an L3 network connection is established between each TOR switch and each physical gateway. However, all physical gateways are virtualized into one logical gateway VTEP to communicate with the external network. Only one VXLAN tunnel is established between a TOR switch and the logical gateway VTEP. Traffic on the tunnel is balanced to multiple physical gateways via the equal-cost multi-path routing (ECMP).
- 5) No VXLAN tunnel or direct physical link is established between physical gateways.
- 6) On the server (virtual machine), only one logical gateway is visible.
- 7) VRF networks are allocated to multiple tenants. Networks of tenants are isolated from each other.

#### 2. SDN controller management:

On the network, the administrator can configure the overlay network topology through the SDN controller and deliver the configurations to VTEPs. The administrator can also monitor the status of the overlay topology and network traffic through the SDN controller.

In addition, the administrator can manage the servers (virtual machines) on the entire network through the cloud management platform. The SDN controller can associate with the cloud management platform to acquire the configuration information (such as IP address and MAC address) of the virtual machine and deliver the configuration information to VTEPs. After the information is delivered, VXLAN forwarding entries are generated and synchronized on VTEPs.

#### 3. VXLAN device automatic-learning capability

VTEPs can automatically learn the MAC address and the ARP routing table of the host if required, which can be used as an emergency solution for the case that the SDN controller fails. The automatic-learning function can be enabled according to the actual deployment.

Figure 2-5

### Deployment

- Deploy the VXLAN bridging function on TOR switches and the VXLAN gateway function on the core switches.
- Configure an IPv4 unicast routing protocol, for example, the OSPF protocol, on all VTEPs (including the TOR and core switches) to ensure that unicast routes are reachable.
- On the core gateways, assign the gateway anycast IP addresses to different routing domains to avoid IP conflicts.

### 2.2.6 Deployment of an EVPN Distributed Network to Be Compatible with Non-EVPN VTEP Devices

#### Scenario

In a data center where an EVPN-based multi-tenant distributed network is deployed, one VTEP device that does not support the BGP-EVPN protocol (for example, a virtual switch supporting the VXLAN protocol) is connected. See the figure below.

BGP is deployed on the TOR and CORE switches. They mutually establish BGP neighbor relationships and support the EVPN routing protocol.

The VXLAN anycast gateways are deployed on the TOR switches and network-wide gateways share the same IP address and MAC address. TOR switches are directly connected to servers (virtual machines) and core switches are connected to external networks.

VXLANs do not need to be deployed on the core switches.

ARP suppression can be configured on TOR switches to curb flooding of ARP packets, and the TOR switches respond to ARP requests from hosts as a proxy.

The ARP proxy function can be enabled on the TOR switches for all or some VXLANs. In this way, L2 traffic in VXLANs is isolated and server communication traffic in the same VXLAN is forwarded at L3 rather than at L2.

ND suppression can be configured on TOR switches to curb flooding of IPv6 ND protocol packets, and the TOR switches respond to IPv6 NS multicast packets from hosts as a proxy.

When the device does not support the data center interconnection tunnel function, BGP-EVEN can be configured on VTEP-1 and all VTEP devices on the network so that VTEP-1 establish VXLAN tunnels with other VTEP devices, thereby forming a full mesh network. The figure below shows the topology.

Figure 2- 6

Note: Blue lines in the figure indicate the VXLAN tunnels that the manually configured VTEP-1 establishes with other VTEPs.

### Deployment

- Configure an IPv4 unicast routing protocol (such as OSPF) on switches to ensure that unicast routes are reachable.
- Configure the BGP routing protocol (supporting EVPN) on the TOR and core switches so that the switches establish neighbor relationships mutually.
- Deploy the VXLAN gateway on the TOR switches and the VXLAN bridge on VTEPs.
- Configure core switches to interconnect to external networks at L3.
- (Optional) Deploy ARP suppression on the TOR switches.
- (Optional) Deploy ARP proxy on the TOR switches.
- (Optional) Deploy IPv6 ND suppression on the TOR switches.

## 2.2.7 Deployment of L2 Subinterfaces to Access a VXLAN

### Scenario

A server can access a VXLAN through an L2 subinterface and the access using other subinterfaces is not affected.

Figure 2-7

- On the TOR, configure the VLAN or untagged access mode for subinterfaces and configure a VXLAN instance (that is, gateway).

### Deployment

- Complete the function configuration on virtual machines on virtual servers as well as on the physical server.
- Create an L2 subinterface on the TOR switch, configure VXLAN encapsulation and VLAN or untagged encapsulation rule for the subinterface.
- Create an overlay router interface on the TOR switch and configure the VXLAN gateway IP address.
- Configure the VXLAN instance to associate with the overlay router interface on the TOR switch to implement VXLAN routing.

## 2.3 Features

### Basic Concepts

#### VXLAN Packet Format

A VXLAN encapsulates the Ethernet frames into UDP packets and transmits them on the IP core network.

The VXLAN defines a VTEP entity, which encapsulates the data generated by the virtual machine into the UDP headers, and sends the data out. After the encapsulation, the MAC address and VLAN information of the virtual machine no longer serves as the basis for data forwarding.

The VTEP entity can be software, a hardware server, or other device. If the VTEP function is directly integrated into a hypervisor (also called virtual machine monitor), all virtual machine traffic is marked with new VXLAN tags and UDP headers before entering the switch. This is equivalent to creating a tunnel between any two virtual machines.

As the VLAN information of the virtual machine is externally invisible, a new VXLAN label (VNI) is added. VNIs replace VLANs to represent different VXLAN segments. Same as the forwarding behavior of VLANs, only the virtual machines with the same VNI in the same VXLAN segment can communicate with each other.

The new UDP header and VNI form a new frame structure. After receiving the data frame sent from the virtual machine, a VTEP encapsulates four elements (which are the VXLAN header, outer UDP header, outer IPv4 header, and outer Ethernet frame header from inside out) to form a new frame header. In the new frame header, the original source and destination MAC addresses, inner VLAN tag, and Ethernet type that are carried by the inner data frame remain the same.

The format of an encapsulated VXLAN frame is as follows:

Figure 2-8

### 2.3.1 Packet Format

#### ✎ VXLAN Header Information

Figure 2-9

**VXLAN Header:**

A VXLAN header has 64 bits. In the design of the current protocol version, the sole purpose of a VXLAN header is to carry the 24-bit VNI assigned by the VTEP.

- Flag (8 bits): The I bit must be set to 1 to indicate a valid VNI, and the R bit must be set to 0.
- VXLAN segment ID/VNI: Includes 24 bits and indicates the VXLAN network identifier. Only the virtual machines that belong to the same VXLAN can communicate with each other.
- Reserved: The 24<sup>th</sup> bit and 8<sup>th</sup> bit are reserved, and are set to 0.

➤ **Outer UDP Header**

Figure 2-10

**Outer UDP Header:**

The definitions of the fields of the UDP header are as follows:

- Source Port: Indicates the source port ID of the UDP packet. Assigned by the VTEP, the source port ID is the result of the hash operation of the L2 header of the data frame. This hash result can serve as the basis for traffic load balancing.
- Dest Port: Indicates the destination port ID. The port ID assigned by the Internet Assigned Numbers Authority (IANA) is 4789.
- UDP Length: Indicates the length of the UDP header.
- UDP Checksum: Indicates the UDP checksum, which is set to 0 for transmission.

➤ **Outer IP Header**

Figure 2-11

**Outer IPv4 Header:**

The definitions of the fields of the outer IP header are as follows:

- Source IPv4 Address: Identifies the IP address of the VTEP that corresponds to the virtual machine.
- Destination IPv4 Address: Indicates the unicast or multicast IP address. If it is a unicast IP address, it indicates the IP address of the VTEP corresponding to the virtual machine to be communicated with.

The IP address of the outer IP header is no longer the address of the virtual machines of both communication parties, but the address of the VTEPs at both ends of the tunnel. If the hypervisor directly takes over the work of the VTEP, the IP address is the IP address of the NIC of the server that runs the hypervisor. If the VTEP is an access switch, the IP address is the IP address of an egress interface or the IP address of an L3 switch virtual interface (SVI).

📄 **Outer Ethernet Header**

Figure 2-12

Outer Ethernet Header:

The definitions of the fields of the outer Ethernet header are as follows:

- Destination MAC address: Next-hop MAC address directed to the IP address of the destination VTEP.
- Source MAC address: MAC address of the local VTEP.
- VLAN tag: Optional.

**2.3.2 Forwarding Model**

📄 **VXLAN Bridging Principle**

VXLAN encapsulates Ethernet packets within UDP packets to transmit them on the IP network. On the receiver, the VXLAN packets are decapsulated into Ethernet packets and then forwarded, as shown in Figure 2-13.

Figure 2-13

- Switch TOR1 receives the common Ethernet packet, and then encapsulates the packet into a VXLAN packet.
- The VXLAN packet is forwarded in the IP core network. As shown in Figure 2-13, R forwards the VXLAN packet.
- Switch TOR2 receives the VXLAN packet, and then decapsulates and forwards it at L2 of the LAN.

**Overview**

Feature	Description
VXLAN Bridging and Forwarding	Encapsulates broadcast, multicast, and unknown unicast packets into IP multicast packets to realize flooding. The well-known unicast packets are encapsulated and forwarded by searching the VXLAN address table for the MAC address and IP address.

**📌 VXLAN Routing Principle**

VXLANs interconnect with each other through the VXLAN IP gateway, as shown in Figure 2-14.

Figure 2-14

- To implement cross-VXLAN communication, Server A first sends a packet to the IP gateway, which is deployed on TOR3.
- The packet sent by Server A is encapsulated by TOR1 into a VXLAN packet and then sent to TOR3.
- After receiving the VXLAN packet, TOR3 finds that the destination MAC address is the local MAC address and sends the packet to TOR2 after VXLAN routing.
- After receiving the packet from TOR3, TOR2 decapsulates the packet and sends it to Server B.

**Overview**

Feature	Description
VXLAN Routing and Forwarding	Implements cross-VXLAN communication and supports communication between a conventional IP network and a VXLAN. A VXLAN router can serve as a VXLAN IP gateway.

**2.3.3 Forwarding Process**

**Working Principle**

As shown in Figure 2-15, three servers use a VXLAN to achieve L2 interconnection on the IP network. The VXLAN VNI is 100.

Figure 2-15

The VXLAN packet forwarding process is described by using an example in which Server A sends an Address Resolution Protocol (ARP) request to Server B and Server B returns an ARP response.

Figure 2-16

- ✔ Server A sends an ARP request, which is a broadcast packet. After receiving the ARP request, switch TOR1 floods the broadcast packet in tunnel header replication mode, encapsulates it into two unicast packets, and sends them to TOR2 and TOR3 through tunnels. (Switch TOR1 floods the broadcast packet to all tunnels. The tunnel between TOR1 and TOR2, and tunnel between TOR1 and TOR3 are created. )
- ✔ The IP core network forwards the multicast VXLAN packet.

Figure 2-17

- After receiving the VXLAN packet, TOR3 decapsulates the packet into an Ethernet packet and implements VXLAN address learning (the VXLANID is 100, the MAC address is 0000.0000.0001, and the IP address is 192.168.1.100).

Figure 2-18

- After receiving the VXLAN packet, TOR2 decapsulates the packet into an Ethernet packet, implements address learning (the VXLAN ID is 100, the MAC address is 0000.0000.0001, and the IP address is 192.168.1.100) and forwards the packet. Then, Server B receives the ARP request packet and returns a response packet.

Figure 2-19

- After receiving the ARP response packet from Server B, TOR2 searches the address table and finds that the destination IP address is 192.168.1.100. Then, TOR2 encapsulates the packet into a unicast VXLAN packet (the outer source IP address is 192.168.2.100) destined for the switch at 192.168.1.100.

Figure 2-20

- ✔ The IP core network forwards the VXLAN packet.
- ✔ TOR1 receives the ARP response packet encapsulated in the VXLAN, decapsulates the packet into an Ethernet packet, implements VXLAN address learning (the VXLAN ID is 100, the MAC address is 0000.0000.0002, and the IP address is 192.168.2.100), and forwards the packet. Then, Server A receives the ARP response packet.

📌 **Multicast VXLAN Packet Flooding**

A VXLAN uses multicast packets to flood broadcast, multicast, and unknown unicast packets. After receiving an ARP request packet, TOR1 encapsulates the packet into a multicast VXLAN packet and sends it to TOR2 and TOR3, as shown in Figure 2-21.

Figure 2-21

### ↘ VTEP Address Learning

As shown in Figure 2-21, in the process of using multicast packets to flood broadcast, multicast, and unknown unicast packets, TOR2 and TOR3 learn the VTEP information during decapsulation, and therefore establish neighbor relationships.

#### Related Configuration

### ↘ Configuring VXLAN Type Instance

No VXLAN instance is configured on the switches by default.

Run the `vxlan vni-number` command to create a VXLAN instance.

### ↘ Configuring VLAN Associated with VXLAN Instance

Run the `extend-vlan vlan-id` command in VXLAN instance configuration mode to configure the associated VLAN.

## 2.4 Configuration

### 2.4.1 Configuring VXLAN SDN

#### Configuration Effect

- Create a VXLAN instance and associate it with the overlay router interface and overlay tunnel interface. Provide the VXLAN routing (IP gateway) function to achieve cross-VXLAN communication. The VXLAN configurations can be delivered by the SDN controller over communication mechanisms such as Network Configuration Protocol (NETCONF), or can be implemented by CLI configuration.
- Configure the anycast gateway and an anycast MAC address to provide centralized anycast all-active gateway function. The centralized anycast all-active gateways serve as one logical gateway (VTEP) to communicate with external devices and use the same VTEP IP address. Only one tunnel is configured between each TOR bridge device and the logical gateway. Packets are balanced to physical gateways via the underlay ECMP to achieve the gateway all-active function.
- Enable the SDN controller to deliver the host routes and VXLAN forwarding flow table to the gateways and the gateways generate routes and entries through automatic learning. You can run the configuration commands to enable or disable the automatic learning function on the gateways. When the SDN controller malfunctions, the automatic learning function ensures that the VXLAN works normally.

#### Notes

- The VXLAN configurations can be delivered by the SDN controller over communication mechanisms such as NETCONF, or can be implemented by CLI configuration. Only configuration delivery from the SDN controller is recommended in normal cases.
- The VXLAN instances require support from existing unicast routes on the network. Therefore, an IPv4 unicast routing protocol, for example, the OSPF protocol, must be configured on the network devices.
- On the centralized anycast gateways, assign the gateway anycast IP addresses to different routing domains to avoid IP conflicts.

#### Configuration Steps

### ↘ Creating VXLAN Instances

- Mandatory.

### ↘ Creating Overlay Router Interfaces

- Mandatory for VXLAN gateways.

### ↘ **Configuring Overlay Router Interfaces as Anycast**

- Mandatory for centralized anycast gateways.

### ↘ **Configuring Anycast MAC Address**

- Mandatory for centralized anycast gateways.

### ↘ **Configuring Overlay Tunnel**

- Mandatory.

### ↘ **Configuring Source and Destination IP Addresses for Overlay Tunnel**

- Mandatory.

### ↘ **Associating VXLAN Instance with Overlay Router Interface**

- Mandatory for gateways.

### ↘ **Associating VXLAN Instance with VLAN**

- Mandatory for TOR bridges.

### ↘ **Associating VXLAN Instance with Overlay Tunnel**

- Mandatory.
- This is used to statically designate a VXLAN tunnel.

### ↘ **Configuring Storm Control of VXLAN Instances**

- Optional.
- This function is required only when the storm rate needs to be limited based on VXLAN instances.

### ↘ **Configuring Static VXLAN MAC Address Table**

- Optional. The VXLAN MAC address table delivered by the SDN controller is represented as a static VXLAN MAC address table.
- You can also configure the static VXLAN MAC address table via CLI configuration.

### ↘ **Configuring VXLAN UDP Destination Port**

- Optional. As the VXLAN UDP destination port used by early devices may not be Port 4789, you can run this command to achieve compatibility. In addition, you can also run this command to customize the VXLAN UDP destination port.
- The VXLAN UDP destination port 4789 designated by IANA is used by default.

### ↘ **Enabling ARP Automatic Learning**

- Optional. ARP automatic learning is enabled by default.
- After the ARP automatic learning function is enabled, the gateways can automatically learn the ARP entries without relying on the SDN control to deliver.

### ↘ **Enabling IPv6 ND Automatic Learning**

- Optional. IPv6 ND automatic learning is enabled by default.

- After the IPv6 ND automatic learning function is enabled, the device can automatically learn the host ND entries, with no need to thoroughly rely on ND entries delivered by the SDN controller.

### Verification

After SDN-VXLAN is enabled, virtual machines can communicate with each other.

- Run the **show vxlan vni-number** command to check whether the VXLAN devices can learn their mutual VTEP neighbor relationships.
- Run the **show vxlan mac** command to check whether the VXLAN MAC address is learned.
- Run the **show arp** command to check whether all local/remote entries are learned. Run the **show ip route** command to check whether the routes of VXLAN IP gateways are learned.
- Run the **show ipv6 neighbors** command to check whether all local/remote IPv6 ND entries are learned. Run the **show ipv6 route** command to check whether the routes of the VXLAN IPv6 gateways are learned.
- Run the **show vxlan udp-port** command to display the VXLAN UDP destination port.

### Related Commands

#### ▾ Creating or Entering VXLAN Instances

<b>Command</b>	<b>vxlan vni-number</b>
<b>Parameter Description</b>	<i>vni-number</i> : Indicates the VNI. The value ranges from 1 to 16777215.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ▾ Associating VXLAN Instance with VLAN

<b>Command</b>	<b>extend-vlan vlan-id-list</b>
<b>Parameter Description</b>	<i>vlan-id-list</i> : Indicates the VLAN ID queue. The VLAN ID ranges from 1 to 4094.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Use this command to associate the VXLAN instance with the VLAN. After receiving the VLAN packet, the device will be associated with the VLAN instance.

#### ▾ Creating Overlay Router Interfaces

<b>Command</b>	<b>interface OverlayRouter port-id</b>
<b>Parameter Description</b>	<i>port-id</i> : Indicates the ID of an overlay router interface. The ID ranges from 1 to 16,777,215.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Similar to SVI in a VLAN, this interface serves as the VXLAN IP gateway in the VXLAN routing environment.

#### ▾ Configuring VRF Network for Overlay Router Interface

<b>Command</b>	<b>vrf forwarding vrf-name</b>
----------------	--------------------------------

<b>Parameter Description</b>	<i>vrf-name</i> : Indicates the VRF network to which the overlay router interface belongs.
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	Allocate VRF networks to different VXLAN tenants. The traffic of VXLAN instances of different VRF networks is isolated from each other.

#### ↘ Configuring IP Address for Overlay Router Interface

<b>Command</b>	<b>ip address</b> <i>ip-address mask</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IP address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	Similar to the IP address of the SVI in a VLAN, this IP address serves as the address of the VXLAN IP gateway in the VXLAN routing environment.

#### ↘ Configuring an IPv6 Address for the Overlay Router Interface

<b>Command</b>	<b>ipv6 address</b> <i>ip-address mask</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv6 address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	This IPv6 address serves as the VXLAN IPv6 gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.

#### ↘ Configuring the Overlay Router Interface as an Anycast Interface

<b>Command</b>	<b>anycast-gateway</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	Configure the gateway as an anycast gateway.

#### ↘ Associating VXLAN Instance with Overlay Router Interface

<b>Command</b>	<b>router-interface</b> <i>interface-name</i>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the name of the overlay router interface.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Different VXLANs cannot be associated with the same overlay router interface.

#### ↘ Configuring Virtual MAC Address for Anycast Gateways

<b>Command</b>	<b>fabric anycast-gateway-mac</b> <i>mac-addr</i>
<b>Parameter Description</b>	<i>mac-addr</i> : Indicates the MAC address. The format is xxxx.xxxx.xxxx.

<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	All gateways on which the anycast function is enabled use this MAC address as the gateway MAC address. The virtual MAC address for an anycast gateway must not be the same as the local MAC address or the same as the MAC address of any device on the overlay network.

### ↘ Creating Overlay Tunnel Interfaces

<b>Command</b>	<b>interface OverlayTunnel</b> <i>port-id</i>
<b>Parameter Description</b>	<i>port-id</i> : Indicates the ID of the overlay tunnel interface. The ID ranges from 1 to 6144.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This interface is used to statically create an overlay tunnel. You can run the <b>tunnel-interface</b> command to associate it with a VXLAN.

### ↘ Configuring Source IP Address for Tunnel of Overlay Tunnel Interface

<b>Command</b>	<b>tunnel source</b> <i>ip-address</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the source IP address of a tunnel.
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	Use this command to designate a source IP address for the overlay tunnel. Designate this IP address as the outer source IP address of a packet for encapsulation and forwarding.

### ↘ Configuring Destination IP Address for Tunnel of Overlay Tunnel Interface

<b>Command</b>	<b>tunnel destination</b> <i>ip-address</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the destination IP address of a tunnel.
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	Use this command to designate a destination IP address for the overlay tunnel. Designate this IP address as the outer destination IP address of a packet for encapsulation and forwarding. The destination IP address of the tunnel is globally unique. Different overlay tunnels cannot be configured with the same destination IP address. Otherwise, a conflict occurs.

### ↘ Associating VXLAN Instance with Overlay Tunnel Interface

<b>Command</b>	<b>tunnel-interface</b> <i>interface-name</i>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the name of the overlay tunnel interface.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Use this command to designate the VXLAN VTEP statically.

### ↘ Configuring Storm Control of VXLAN Instances

<b>Command</b>	<b>storm-control</b> { <b>broadcast</b>   <b>multicast</b>   <b>unicast</b> } [ <i>kbps-value</i>   <b>pps</b> <i>pps-value</i> ]
----------------	---

<b>Parameter</b>	<i>kbps-value</i> : Indicates the rate limit value (unit: kbit/s).
<b>Description</b>	<i>pps-value</i> : Indicates the rate limit value (unit: packet count/s).
<b>Command</b>	VXLAN configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	Configure the storm control when the storm rate needs to be limited based on the VNI.

### 📌 Configuring Static VXLAN MAC Address Table

<b>Command</b>	<b>vxlan mac static</b> <i>mac-addr</i> vni <i>vxlan-id</i> interface <i>interface-name</i>
<b>Parameter</b>	<i>mac-addr</i> : Indicates the MAC entry address. The format is xxxx.xxxx.xxxx.
<b>Description</b>	<i>vxlan-id</i> : Indicates the VNI of the MAC entry. <i>interface-name</i> : Indicates the next hop egress of the MAC table. It can be an overlay tunnel interface, an Ethernet interface, or an aggregate port (AP). <i>vid</i> : Indicates the ID of a VLAN to which the MAC entry belongs.
<b>Command</b>	Global configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. Use this command to deliver the static VXLAN MAC entries via the SDN controller or configure the static VXLAN MAC entries via CLI static configuration. This command is mainly used for setting the host forwarding table.</li> <li>2. When the next-hop interface is not an overlay tunnel interface, a VID must be configured and the VID is not required for overlay tunnel interfaces.</li> </ol>

### 📌 Configuring VXLAN UDP Destination Port

<b>Command</b>	<b>vxlan udp-port</b> <i>port-number</i>
<b>Parameter</b>	<i>port-number</i> : Indicates the UDP destination port ID. The value ranges from 0 to 65535 and the default value is 4789.
<b>Description</b>	
<b>Command</b>	Global configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	Note that the UDP destination port cannot be same as commonly used UDP ports.

### Configuration Example

-  Only configuration related to the VXLAN is described below.
-  Only IPv4 configuration is used as an example below and the IPv6 scenario configuration is largely the same as the IPv4 scenario configuration.

### 📌 VXLAN Configuration Instance

**Scenario**  
**Figure 2- 22**

**Configuration Steps**

- Configure an IPv4 unicast routing protocol such as the OSPF protocol on TOR-1, TOR-2, CORE-1, and CORE-2 to ensure that unicast routes are reachable.
- Configure loopback IP addresses on TOR-1, TOR-2, CORE-1, and CORE-2 and distribute packets via the unicast routing protocol. The VTEP IP addresses of CORE-1 and CORE-2 must be the same and be allocated to different routing domains.
- Configure a VXLAN on the virtual server and designate the gateway address of the virtual machine. .
- Establish a BGP neighbor relationship between CORE-1 and CORE-2 and configure the BGP-EVPN routing protocol on them.

The following configuration can be delivered by the SDN controller:

- Create VXLAN instances VXLAN 10 and VXLAN 20 on TOR-1, and associate them with VLAN 10 and VLAN 20 respectively. Configure the address learning mode as SDN controller advertisement. Configure two overlay tunnels to connect TOR-1 with TOR-2 and CORE. Associate VXLAN 10 and VXLAN 20 with the two tunnels separately.
- Create VXLAN instance VXLAN 20 on TOR-2 and associate it with VLAN 20. Configure the address learning mode as SDN controller advertisement. Configure two overlay tunnels to connect TOR-2 with TOR-1 and CORE-2. Associate VXLAN 20 with the two tunnels.
- Create VXLAN instances VXLAN 10 and VXLAN 20 on CORE-1. Configure the address learning mode as SDN controller advertisement. Configure the anycast MAC address. Configure two overlay router gateway interfaces and

	<p>configure their IP addresses as 10.1.1.1/24 and 10.1.2.1/24 respectively. Associate VXLAN 10 with the overlay router gateway interface with the IP address 10.1.1.1/24. Associate VXLAN 20 with the overlay router gateway interface with the IP address 10.1.2.1/24. Configure two overlay tunnels to connect CORE-1 with TOR-1 and TOR-2. Associate VXLAN 10 and VXLAN 20 with the two tunnels separately.</p> <p>Enable the synchronization function on all-active VXLAN gateways to synchronize the automatically learned entries between the gateways.</p> <ul style="list-style-type: none"> <li>● The configuration of CORE-2 is same with that of CORE-1.</li> </ul>
<b>TOR1</b>	<pre>TOR1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. TOR1(config)#interface loopback0 TOR1(config-if-Loopback 0)# ip address 1.1.1.1 255.255.255.255 TOR1(config-if-Loopback 0)# exit TOR1(config)# interface OverlayTunnel 1 TOR1(config-if-OverlayTunnel 1)# tunnel source 1.1.1.1 TOR1(config-if-OverlayTunnel 1)# tunnel destination 2.2.2.2 TOR1(config-if-OverlayTunnel 1)# exit TOR1(config)# interface OverlayTunnel 2 TOR1(config-if-OverlayTunnel 2)# tunnel source 1.1.1.1 TOR1(config-if-OverlayTunnel 2)# tunnel destination 3.3.3.3 TOR1(config-if-OverlayTunnel 2)# exit TOR1(config)# vxlan 10 TOR1(config-vxlan)# tunnel-interface OverlayTunnel 1 TOR1(config-vxlan)# tunnel-interface OverlayTunnel 2 TOR1(config-vxlan)# extend-vlan 10 TOR1(config-vxlan)# end TOR1(config)# vxlan 20 TOR1(config-vxlan)# tunnel-interface OverlayTunnel 1 TOR1(config-vxlan)# tunnel-interface OverlayTunnel 2 TOR1(config-vxlan)# extend-vlan 20 TOR1(config-vxlan)# end</pre>
<b>TOR2</b>	<pre>TOR2# configure terminal Enter configuration commands, one per line. End with CNTL/Z. TOR2(config)#interface loopback0 TOR2(config-if-Loopback 0)# ip address 2.2.2.2 255.255.255.255 TOR2(config-if-Loopback 0)# exit TOR2(config)# interface OverlayTunnel 1 TOR2(config-if-OverlayTunnel 1)# tunnel source 2.2.2.2 TOR2(config-if-OverlayTunnel 1)# tunnel destination 1.1.1.1 TOR2(config-if-OverlayTunnel 1)# exit TOR2(config)# interface OverlayTunnel 2 TOR2(config-if-OverlayTunnel 2)# tunnel source 2.2.2.2 TOR2(config-if-OverlayTunnel 2)# tunnel destination 3.3.3.3 TOR2(config-if-OverlayTunnel 2)# exit</pre>

	<pre>TOR2(config)# vxlan 20 TOR2(config-vxlan)# tunnel-interface OverlayTunnel 1 TOR2(config-vxlan)# tunnel-interface OverlayTunnel 2 TOR2(config-vxlan)# extend-vlan 20 TOR2(config-vxlan)# end</pre>
<b>CORE1</b>	<p>Create VXLAN instances VXLAN10 and VXLAN20 on CORE-1. Set the address learning mode to SDN controller advertisement. Configure an anycast MAC address. Configure two overlay router gateway interfaces and set their IP addresses to 10.1.1.1/24 and 10.1.2.1/24 respectively. Configure VXLAN10 to associate with the overlay router gateway interface with the IP address of 10.1.1.1/24. Configure VXLAN20 to associate with the overlay router gateway interface with the IP address of 10.1.2.1/24. Configure two overlay tunnels reachable to TOR1 and TOR2 respectively. Configure VXLAN10 and VXLAN20 to associate with the two tunnels respectively. Configure loopback 1 on both CORE-1 and CORE-2 and set the IP address to 3.3.3.4 and 3.3.3.5 for loopback 1. The two core switches establish a BGP neighbor relationship through loopback 1. Configure the L2VPN EVPN address family activation command.</p> <pre>TOR1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. ## 2.4.2 Configuring VXLAN EVPN

### Configuration Effect

- Enable the control plane learning function to implement VXLAN tunnel learning, MAC address learning, and route learning via control plane protocols, thereby finally implementing VXLAN bridging, VXLAN routing, and data communication between VXLANs and between a VXLAN and an external network.
- Support functions such as anycast gateways, symmetric VXLAN instances, and ARP suppression in EVPN control plane mode.

### Notes

- The VXLAN instances require support from existing unicast routes on the network. Therefore, an IPv4 unicast routing protocol, for example, the OSPF protocol must be configured on the network devices.
- The MP-BGP-EVPN protocol is required for VXLANs to implement VXLAN tunnel learning, MAC address learning, and route learning. Therefore, the devices on the network must complete BGP-related configurations.

### Configuration Steps

#### ▾ Configuring Loopback Interface Associated with Local End

- Mandatory.
- Configure the IP address of a loopback interface as the IP address of the local VTEP. One VTEP device can be associated with only one loopback interface to serve as the VXLAN VTEP IP address.
- If the L3 egress is an overlay router interface during static route configuration, the next-hop IP address cannot be set to the VTEP IP address.

#### ▾ Configuring Virtual MAC Address for Anycast Gateways

- Optional.
- Configure a unified virtual MAC address for all anycast gateways on the network. The anycast function can be enabled on the VXLAN overlay router interface of the local device only after the virtual MAC address is configured.

#### ▾ Configuring ARP Suppression

- Optional.
- After ARP suppression is enabled, the switch responds to the ARP request from the host as a proxy, reducing the flooded ARP data.
- ARP suppression is generally enabled on the TOR bridge devices in a centralized deployment scenario, or on the distributed gateways in a distributed deployment scenario.

### ▾ **Configuring ARP Proxy**

- Optional.
- After ARP suppression is enabled on a VTEP device, you can enable the ARP proxy function on an overlay router interface.
- After ARP proxy is enabled, the VTEP device responds to ARP requests from hosts as a proxy and the MAC address used for proxy response is the gateway MAC address configured on the VTEP device. In this way, the MAC address in the ARP request responses are the MAC address of the VTEP device, and the traffic between hosts in the same VNI is forwarded at L3.

ARP proxy can be enabled only on VXLAN gateways and is generally enabled on distributed gateways in distributed deployment scenarios.

### ▾ **Configuring IPv6 ND Suppression**

- Optional.
- After IPv6 ND suppression is enabled, the VTEP device responds to NS multicast packets from hosts as a proxy, to reduce flooded NS multicast packets on the network.
- IPv6 ND suppression is generally enabled on distributed gateways in distributed deployment scenarios.

### ▾ **Configuring the EVPN Protocol Packet Control Function**

- In symmetric EVPN deployment scenarios, the EVPN protocol packet control function can be configured on TOR switches to reduce the traffic of EVPN packets.

Currently, the EVPN protocol packet control function includes the following:

- Extracting MAC entries from EVPN MAC-IP type-2 routes (ARP entries) on a L2-VPN VXLAN instance
- Extracting MAC entries from EVPN MAC-IPv6 type-2 routes (IPv6 ND entries) on a L2-VNI VXLAN instance
- Banning synchronization of the local MAC address to the remote VTEP through EVPN messages on an L2-VNI VXLAN instance
- Banning delivery of the MAC addresses remotely synchronized through EVPN messages to the local MAC address table on an L2-VNI VXLAN instance
- Stopping an L2-VNI VXLAN instance from generating EVPN type-2 routes

### ▾ **Configuring Remote ARP Packet Learning**

- Mandatory for centralized gateways and not recommended for other devices.
- After the remote ARP packet learning function is enabled, the VXLAN gateways can learn the VXLAN route entries from the encapsulated VXLAN ARP packets received from the VXLAN tunnels.

### ▾ **Configuring Remote IPv6 ND Protocol Packet Learning**

- Mandatory for centralized gateways and not recommended for other devices.
- After the remote IPv6 ND protocol packet learning function is enabled, the VXLAN gateway can learn IPv6 ND entries from VXLAN-encapsulated IPv6 protocol packets received from VXLAN tunnels.

### ▾ **Creating VXLAN Instances**

- Mandatory.

### ▾ **Associating VXLAN Instance with Overlay Router Interface**

- Mandatory for VXLAN gateways.
- Only after the VXLAN is associated with the overlay router interface, the device can provide the VXLAN routing function and serve as a VXLAN IP gateway.

#### ↘ **Associating VXLAN Instance with VLAN**

- Mandatory for VXLAN devices directly connected to the host.
- Only after a VLAN is associated with a VXLAN instance, packets of the VLAN can be encapsulated into VXLAN packets and then forwarded.
- After a VLAN is associated with a VXLAN, all packets of the VLAN will be encapsulated into VXLAN packets. Therefore, an SVI cannot be used as the VLAN IP gateway on the device.

#### ↘ **Configuring Storm Control of VXLAN Instances**

- Optional.
- This function is required only when the storm rate needs to be limited based on VXLAN instances.

#### ↘ **Configuring VXLAN UDP Destination Port**

- Optional. As the VXLAN UDP destination port used by early devices may not be Port 4789, you can run this command to achieve compatibility. In addition, you can also run this command to customize the VXLAN UDP destination port.
- The VXLAN UDP destination port 4789 designated by IANA is used by default.

#### ↘ **Configuring Symmetric Instances**

- Optional.
- Symmetric instances need to be configured only in symmetric scenarios. Only one symmetric instance can be configured for each VRF network. After a symmetric instance is configured in a VRF network, L3 forwarding of other asymmetric instances is all switched to the symmetric instance for implementation.

#### ↘ **Configuring Static VXLAN Network Routes**

- Optional.
- Configure the static VXLAN network routes based on VXLAN instances if required.

#### **Verification**

Based on EVPN control plane learning, VXLAN tunnels, VXLAN MAC entries, and VXLAN route entries can be formed. Run the following commands for verification.

- Run the **show vxlan vni-number** command to check whether the local and remote VXLAN devices can learn mutual VTEP neighbor relationships.
- Run the **show vxlan mac** command to check whether the VXLAN MAC address is learned.
- Run the **show arp** command to check whether the ARP entry of the VXLAN IP gateway is learned.
- Run the **show ipv6 neighbors** command to check whether all local/remote IPv6 ND entries are learned.
- Run the **show vxlan udp-port** command to display the VXLAN UDP destination port.

#### **Related Commands**

### ✚ Configuring Loopback Interface Associated with Local End

<b>Command</b>	<b>source loopback loopback-port-id</b>
<b>Parameter Description</b>	<i>Loopback-port-id</i> : Indicates the ID of the loopback interface.
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	The local VTEP IP address is the configured loopback interface IP address.

### ✚ Configuring Virtual MAC Address for Anycast Gateways

<b>Command</b>	<b>fabric anycast-gateway-mac mac-addr</b>
<b>Parameter Description</b>	<i>mac-addr</i> : Indicates the MAC address. The format is xxxx.xxxx.xxxx.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	All gateways on which the anycast function is enabled use this MAC address as the gateway MAC address. The virtual MAC address for an anycast gateway must not be the same as the local MAC address or the same as the MAC address of any device on the overlay network.

### ✚ Configuring Remote ARP Packet Learning

<b>Command</b>	<b>remote arp learn enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the remote ARP packet learning function globally. After this function is enabled, the VXLAN gateways can learn the VXLAN route entries from the encapsulated VXLAN ARP packets received from the VXLAN tunnels.

### ✚ Configuring Remote IPv6 ND Protocol Packet Learning

<b>Command</b>	<b>remote nd learn enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the remote IPv6 ND packet learning function globally. After this function is enabled, the device can learn IPv6 ND entries from the VXLAN-encapsulated IPv6 NS packets received from VXLAN tunnels.

### ✚ Configuring ARP Suppression

<b>Command</b>	<b>arp suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable ARP suppression globally. After ARP suppression is enabled, the switch responds to the ARP requests

from the host as a proxy. The VNI-based ARP suppression may be also supported, depending on the product type. You can configure global ARP suppression or VNI-based ARP suppression based on the actual application scenario.

#### ↘ Configuring VNI-based ARP Suppression

<b>Command</b>	<b>arp suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Enable or disable VNI-based ARP suppression. After ARP suppression is enabled, the switch responds to ARP requests from hosts as a proxy. The global ARP suppression may be also supported, depending on the product type. You can configure global ARP suppression or VNI-based ARP suppression based on the actual application scenario.

#### ↘ Configuring ARP Proxy

<b>Command</b>	<b>route-in-vni</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	After the intra-VNI routing function (ARP proxy) is enabled on an overlay router interface, the VTEP device uses its gateway MAC address to respond to all ARP requests from hosts in the VNI, to which the overlay router interface belongs, when serving as an ARP proxy. In this way, the communication traffic between hosts in the same VNI is forwarded through VXLAN routes.

#### ↘ Configuring Global IPv6 ND Suppression

<b>Command</b>	<b>nd suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the global IPv6 ND suppression function. After IPv6 ND suppression is enabled, the device responds to IPv6 NS multicast packets from hosts as a proxy. The VNI-based IPv6 ND suppression may be also supported, depending on the product type. You can configure global IPv6 ND suppression or VNI-based IPv6 ND suppression based on the actual application scenario.

#### ↘ Configuring VNI-based IPv6 ND Suppression

<b>Command</b>	<b>nd suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Enable or disable the VNI-based IPv6 ND suppression function. After IPv6 ND suppression is enabled, the device responds to IPv6 NS multicast packets from hosts as a proxy. The global IPv6 ND suppression may be also supported, depending on

	the product type. You can configure global IPv6 ND suppression or VNI-based IPv6 ND suppression based on the actual application scenario.

#### ↘ Extracting MAC Entries from EVPN MAC-IP Type-2 Routes (ARP Entries)

<b>Command</b>	<b>evpn arp mac-learning enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device parses one ARP entry and one MAC entry from a MAC-IP type-2 route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is disabled by default and the device parses one ARP entry but no MAC entry from a MAC-IP type-2 route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only the EVPN entry parsing of the VXLAN instance. Other VXLAN instances, for which this command is not configured, are not affected.</p> <p>This command can be used in combination with the <b>evpn mac advertise disable</b> command. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IP type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IP type-2 routes.</p> <p>This command is configured on L2-VNI VXLAN instances.</p>

#### ↘ Extracting MAC Entries from EVPN MAC-IPv6 Type-2 Routes (IPv6 ND Entries)

<b>Command</b>	<b>evpn nd mac-learning enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device parses one IPv6 ND entry and one MAC entry from a MAC-IPv6 type-2 route (IPv6 ND entry) synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is disabled by default and the device parses one IPv6 ND entry but no MAC entry from a MAC-IPv6 type-2 route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only the EVPN entry parsing of the VXLAN instance. Other VXLAN instances, for which this command is not configured, are not affected.</p> <p>This command can be used in combination with the <b>evpn mac advertise disable</b> command. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IPv6 type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IPv6 type-2 routes.</p> <p>This command is configured on L2-VNI VXLAN instances.</p>

#### ↘ Configuring an L2-VNI VXLAN Instance Not to Synchronize the Local MAC Address to the Remote VTEP Through EVPN Messages

<b>Command</b>	<b>evpn mac advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode

<b>Mode</b>	
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP can learn the MAC entry from the MAC-only type-2 route.</p> <p>After this command is configured, the device does not generate VXLAN-EVPN MAC-only type-2 routes based on MAC entries, and therefore, it will not advertise MAC-only type-2 routes to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates MAC-only type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate MAC-only type-2 routes.</p> <p>This command can be used in combination with the <b>evpn arp mac-learning enable</b> and <b>evpn nd mac-learning enable</b> commands. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IP type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IP or MAC-IPv6 type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

#### ↘ Configuring an L2-VNI VXLAN Instance Not to Deliver MAC Addresses Remotely Synchronized Through EVPN Messages to the Local MAC Address Table

<b>Command</b>	<b>evpn mac inactive</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device does not learn MAC entries from VXLAN-EVPN type-2 routes (MAC-IP or MAC-only type-2 routes) synchronized from neighbors.</p> <p>This command is not configured on a device by default. The device learns MAC entries from VXLAN-EVPN type-2 routes synchronized from neighbors.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance learns MAC entries from VXLAN-EVPN type-2 routes. Other VXLAN instances, for which this command is not configured, can still learn MAC entries.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

#### ↘ Configuring an L2-VNI VXLAN Instance Not to Generate EVPN Type-2 Routes

<b>Command</b>	<b>evpn rt-2 advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP learns the MAC entry from the MAC-only type-2 route. In addition, the device generates one MAC-IP type-2 route through the VXLAN-EVPN protocol based on a locally learned ARP entry and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the ARP entry and host route from the MAC-IP type-2 route. The device generates one MAC-IPv6 type-2 route through the VXLAN-EVPN protocol based on a locally learned IPv6 ND entry, and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the</p>

	<p>IPv6 ND entry and host route from the MAC-IPv6 type-2 route. After this command is configured, the MAC entries, ARP entries, and IPv6 ND entries of the device are not used to generate VXLAN-EVPN type-2 routes and therefore, no type-2 route is advertised to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>
--	---

### ↘ Creating Overlay Router Interfaces

<b>Command</b>	<b>interface OverlayRouter</b> <i>port-id</i>
<b>Parameter Description</b>	<i>port-id</i> : Indicates the ID of an overlay router interface. The ID ranges from 1 to 16,777,215.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Similar to SVI in a VLAN, this interface serves as the VXLAN IP gateway in the VXLAN routing environment.

### ↘ Configuring IP Address for Overlay Router Interface

<b>Command</b>	<b>ip address</b> <i>ip-address mask</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IP address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Similar to the IP address of the SVI in a VLAN, this IP address serves as the address of the VXLAN IP gateway in the VXLAN routing environment.

### ↘ Configuring an IPv6 Address for the Overlay Router Interface

<b>Command</b>	<b>ipv6 address</b> <i>ip-address mask</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv6 address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	This IPv6 address serves as the VXLAN IPv6 gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.

### ↘ Associating Overlay Router Interface with VRF Network

<b>Command</b>	<b>vrf forwarding</b> <i>table name</i>
<b>Parameter Description</b>	<i>Table name</i> : Indicates the VRF network associated with the overlay router interface.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	Use this command to associate an overlay router interface with a VRF network in the VXLAN routing environment, to implement VXLAN L3 route isolation.

### ↘ Creating or Entering VXLAN Instances

<b>Command</b>	<b>vxlan vni-number</b>
<b>Parameter Description</b>	<i>vni-number</i> : Indicates the VNI. The value ranges from 1 to 16777215.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

### ▾ Configuring Symmetric Instances

<b>Command</b>	<b>symmetric</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	No symmetric instance is configured by default. Symmetric instances are used to manage the L3 forwarding entries of all asymmetric instances of the VRF networks associated with the symmetric instances.

### ▾ Associating VXLAN Instance with Overlay Router Interface

<b>Command</b>	<b>router-interface interface-name</b>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the name of the overlay router interface.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Different VXLANs cannot be associated with the same overlay router interface.

### ▾ Configuring VXLAN UDP Destination Port

<b>Command</b>	<b>vxlan udp-port port-number</b>
<b>Parameter Description</b>	<i>port-number</i> : Indicates the UDP destination port ID. The value ranges from 0 to 65535 and the default value is 4789.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	Note that the UDP destination port cannot be same as commonly used UDP ports.

### ▾ Configuring Storm Control of VXLAN Instances

<b>Command</b>	<b>storm-control {broadcast   multicast   unicast} [<i>kbps-value</i>   <i>pps pps-value</i>]</b>
<b>Parameter Description</b>	<i>kbps-value</i> : Indicates the rate limit value (unit: kbit/s). <i>pps-value</i> : Indicates the rate limit value (unit: packet count/s).
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Configure the storm control when the storm rate needs to be limited based on the VNI.

### Configuration Example

-  Only configuration related to the VXLAN is described below.
-  Only IPv4 configuration is used as an example below and the IPv6 scenario configuration is largely the same as the IPv4 scenario configuration.

### 2.4.2.1 Configuring EVPN-based Multi-tenant Centralized Scenario

<p><b>Scenario</b> Figure 2- 23</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an IPv4 unicast routing protocol such as the OSPF protocol on CORE, TOR-1, and TOR-2 to ensure that unicast routes are reachable.</li> <li>● Configure the BGP-EVPN routing protocol on CORE, TOR-1, and TOR-2 to establish BGP neighbor relationships between the three devices and to support the EVPN protocol family.</li> <li>● Configure the EVI for BGP-EVPN on CORE, TOR-1, and TOR-2. For details, see <i>BGP-EVPN Configuration Guide</i>.</li> <li>● Configure a VXLAN on the virtual server and designate the gateway address of the virtual machine.</li> <li>● Associate the VTEP with the loopback interface on TOR-1, TOR-2, and CORE to establish tunnels.</li> <li>● Create VXLAN instances on TOR-1, TOR-2, and CORE and associate the VXLAN instances with VLANs.</li> <li>● Create overlay router interfaces and configure the VXLAN gateway IP address on CORE. Configure different VRF networks for different overlay router interfaces to determine their respective tenants.</li> <li>● Associate VXLAN instances with overlay router interfaces on CORE to realize VXLAN routing.</li> <li>● Enable the remote ARP packet learning function on CORE to generate VXLAN routing entries dynamically.</li> <li>● (Optional) Configure ARP suppression on TOR-1 and TOR-2 to reduce the ARP packets entering the VXLAN.</li> </ul>
<p><b>HOST</b></p>	<p>Configuring the IP address and gateway according to Figure 2-23 (the detailed configuration on the server is omitted herein).</p>
<p><b>CORE</b></p>	<p>The configuration of the OSPF, and Ethernet interface is omitted herein. The following describe only the VXLAN configuration.</p> <pre> CORE# configure terminal Enter configuration commands, one per line. End with CNTL/Z. ## 2.4.2.2 Configuring EVPN-based Multi-tenant Centralized All-active Anycast Gateway Scenario

<p><b>Scenario</b> Figure 2- 24</p>	
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure an IPv4 unicast routing protocol such as the OSPF protocol on CORE, TOR-1, and TOR-2 to ensure that unicast routes are reachable.</li> <li>● Configure the BGP-EVPN routing protocol on CORE, TOR-1, and TOR-2 to establish BGP neighbor relationships between the three devices and to support the EVPN protocol family.</li> <li>● Configure the EVI for BGP-EVPN on CORE, TOR-1, and TOR-2. For details, see <i>BGP-EVPN Configuration Guide</i>.</li> <li>● Configure a VXLAN on the virtual server and designate the gateway address of the virtual machine. (Omitted).</li> <li>● Associate the VTEP with the loopback interface on TOR-1, TOR-2, and CORE to establish tunnels.</li> </ul> <p>Note that the same loopback interface IP address needs to be configured on CORE1 and CORE2 as the VTEP IP address for tunnel establishment.</p> <p>After the loopback interface IP address is configured, no tunnel is established between CORE1 and CORE2.</p> <p>On TOR1, only one tunnel whose VTEP IP address is 1.1.1.1 and one tunnel whose VTEP IP address is 3.3.3.3 can be viewed.</p> <p>On TOR2, only one tunnel whose VTEP IP address is 1.1.1.1 and one tunnel whose VTEP IP address is 2.2.2.2 can be viewed.</p> <p>On CORE1, only one tunnel whose VTEP IP address is 2.2.2.2 and one tunnel whose VTEP IP address is 3.3.3.3 can be viewed.</p> <p>On CORE2, only one tunnel whose VTEP IP address is 2.2.2.2 and one tunnel whose VTEP IP address is 3.3.3.3 can be viewed.</p>

	<ul style="list-style-type: none"> <li>● Create VXLAN instances on TOR-1, TOR-2, and CORE and associate the VXLAN instances with VLANs.</li> <li>● Create overlay router interfaces and configure the VXLAN gateway IP address on CORE. Configure different VRF networks for different overlay router interfaces to determine their respective tenants. Associate VXLAN instances with overlay router interfaces to realize VXLAN routing.</li> </ul> <p>Note that the overlay router interface configurations on CORE1 and CORE2 must be the same. That is, the IP addresses and masks configured for the overlay router interfaces associated with the same VXLAN instance must be the same on CORE1 and CORE2 and belong to the same tenant (VRF).</p> <p>In addition, an anycast gateway must be configured for all overlay router interfaces.</p> <ul style="list-style-type: none"> <li>● Configure the same anycast gateway MAC address on CORE1 and CORE2 to ensure that all VXLAN anycast gateways on CORE use the same MAC address.</li> <li>● Enable the remote ARP packet learning function on CORE to generate VXLAN routing entries dynamically.</li> <li>● (Optional) Configure ARP suppression on TOR-1 and TOR-2 to reduce the ARP packets entering the VXLAN.</li> </ul>
<b>HOST</b>	Configure the IP address and gateway according to Figure 2-24 (the detailed configuration on the server is omitted herein).
<b>CORE</b>	<p>The configuration of the OSPF and Ethernet interface is omitted herein. The following describes only the VXLAN configuration.</p> <p><b>Note: VXLAN configuration on CORE1 and CORE2 is the same. The following configuration applies to CORE1 and CORE2:</b> Configure loopback 1 on both CORE1 and CORE2 and set the IP address to 1.1.1.2 and 1.1.1.3 for loopback 1. The two core switches establish a BGP neighbor relationship through loopback 1. Configure the L2VPN EVPN address family activation command.</p> <pre> CORE# configure terminal Enter configuration commands, one per line. End with CNTL/Z. ```

**Common Errors**

-  When symmetric deployment is disabled, all TOR switches of the same VRF network must have all the VXLAN gateways of the VRF network configured on them. For example, VRF-10 includes VXLAN 10 and VXLAN 20, and therefore all gateways of VXLAN 10 and VXLAN 20 must be configured on TOR-1 and TOR-2. Otherwise, VXLAN 10 and VXLAN 20 cannot communicate with each other. If you expect to deploy only required gateways instead of deploying all gateways on all TOR switches, apply symmetric deployment. For details, see section “Configuring EVPN-based Multi-tenant Distributed Scenario (Symmetric Deployment).”
-  Make sure that the global anycast MAC address is not the same as that of any device on the VXLAN.

### 2.4.2.4 Configuring EVPN-based Multi-tenant Distributed Scenario (Symmetric Deployment)

<b>Scenario</b>	
<b>Figure 2- 26</b>	

**Configuration Steps**

- Configure an IPv4 unicast routing protocol such as the OSPF protocol on CORE, TOR-1, and TOR-2 to ensure that unicast routes are reachable.
- Configure the BGP-EVPN routing protocol on CORE, TOR-1, and TOR-2 to establish BGP neighbor relationships between the four devices and to support the EVPN protocol family.
- Configure the EVI for BGP-EVPN on TOR-1 and TOR-2. For details, see *BGP-EVPN Configuration Guide*.
- Configure a VXLAN on the virtual server and designate the gateway address of the virtual machine.
- Associate the VTEP with loopback interface on TOR-1 and TOR-2 to establish tunnels.
- Configure the anycast gateway MAC address on TOR-1 and TOR-2 to ensure that all VXLAN anycast gateways on the network use the same MAC address.
- Create VXLAN 10, VXLAN20, and VXLAN 100 on TOR-1 and associate them with VLANs.
- Create VXLAN 10 and VXLAN 100 on TOR-2 and associate them with VLANs.
- Create overlay router interfaces for VXLAN 10, VXLAN 20, and VXLAN 100 on TOR-1 and TOR-2 (TOR-2 do not have VXLAN 20), and configure the VXLAN gateway IP address for them. Configure different VRF networks for different overlay router interfaces to determine their respective tenants. Configure the anycast gateway to ensure that all VXLAN gateways on the network use the same IP address and MAC address. As the anycast gateway function is enabled, the overlay router interfaces associated with the same VXLAN on TOR-1 and TOR-2 must be configured with the same VXLAN gateway IP address.
- Create VXLAN 11 and VXLAN 101 on TOR-1 and TOR-2 and configure them as symmetric VXLANs to serve as L3 routing VXLAN of the corresponding VRF networks. L3 routes between all VXLANs of the same VRF network are advertised via the symmetric VXLANs. In addition, the symmetric VXLANs are also used for L3 routing and forwarding.
- Create overlay router interfaces for VXLAN 11 and VXLAN 101 on TOR-1 and TOR-2. Configure different VRF networks for the overlay router interfaces. VXLAN 11 and VXLAN 101 serve as the symmetric VXLANs of the corresponding VRF networks.
- Associate VXLAN instances with overlay router interfaces on TOR-1 and TOR-2 to realize VXLAN routing.
- (Optional) Configure ARP suppression on TOR-1 and TOR-2 to reduce the ARP packets entering the VXLAN.

	<ul style="list-style-type: none"> <li>● (Optional) Configure ARP proxy on the overlay router interfaces belonging to the L2-VNIs (VXLANs 10, 20, and 100) on TOR-1 and TOR-2 so that the traffic of hosts in the same VXLAN is forwarded at L3. This function needs to be enabled together with ARP suppression. The configuration command is <b>route-in-vni</b>.</li> <li>● (Optional) Configure no synchronization of EVPN entries in ARP proxy deployment scenario: On the L2-VNI VXLAN instances (VXLANs 10, 20, and 100) on TOR-1 and TOR-2, configure not to advertise or receive MAC-only EVPN type-2 routes. <ul style="list-style-type: none"> <li>■ Configure not to advertise EVPN MAC-only type-2 routes to reduce EVPN route synchronization between devices. The configuration command is <b>evpn mac advertise disable</b>.</li> <li>■ Configure not to deliver MAC entries synchronized by EVPNs to reduce the occupancy of hardware entry resources. The configuration command is <b>evpn mac inactive</b>.</li> </ul> </li> </ul> <p>The two commands above can be configured independently and they do not affect each other.</p> <ul style="list-style-type: none"> <li>● (Optional) Configure no synchronization of EVPN entries in scenarios where ARP proxy is not deployed: On the L2-VNI VXLAN instances (VXLANs 10, 20, and 100) on TOR-1 and TOR-2, configure not to advertise EVPN MAC-only type-2 routes and configure to extract MAC addresses from MAC-IP type-2 routes. <ul style="list-style-type: none"> <li>■ Configure not to advertise EVPN MAC-only type-2 routes to reduce EVPN route synchronization between devices. The configuration command is <b>evpn mac advertise disable</b>.</li> <li>■ Configure to extract MAC addresses from MAC-IP type-2 routes so that the device can learn MAC entries even if neighbors do not advertise MAC-only type-2 routes. The configuration command is <b>evpn arp mac-learning enable</b>.</li> </ul> </li> <li>● The two commands above must be used in combination. Otherwise, the device cannot learn MAC entries from neighbors and L2 forwarding cannot be implemented in VXLANs.</li> </ul>
<b>HOST</b>	Configuring the IP address and gateway according to Figure 2-26 (the detailed configuration on the server is omitted herein).
<b>CORE</b>	VXLAN may be not configured on the core switches. The configuration of the OSPF and BGP is omitted herein.

### 2.4.2.6 Configuring EVPN-based Multi-tenant VXLAN Routing Scenario

Scenario  
Figure 2- 28

**Configuration Steps**

- Configure an IPv4 unicast routing protocol such as the OSPF protocol on Border-1, Border-2, TOR-1, and TOR-2 to ensure that unicast routes are reachable.
- Configure the BGP-EVPN routing protocol on Border-1, Border-2, TOR-1, and TOR-2 to establish BGP neighbor relationships between the devices (except between Border-1 and Border-2) and to support the EVPN protocol family.
- Configure the EVI for BGP-EVPN on TOR-1 and TOR-2. For details, see *BGP-EVPN Configuration Guide*.
- Configure a VXLAN on the virtual server and designate the gateway address of the virtual machine.
- Associate the VTEP with the loopback interface on TOR-1, TOR-2, Border-1, and Border-2 to establish tunnels.
- Configure the anycast gateway MAC address on TOR-1 and TOR-2 to ensure that all VXLAN anycast gateways on the network use the same MAC address.
- Create VXLAN 10, VXLAN 20, and VXLAN 30 on TOR-1 and associate them with VLANs.
- Create VXLAN 10, VXLAN 20, and VXLAN 30 on TOR-2 and associate them with VLANs.
- Create VXLAN 90 on Border-1 and associate VXLAN 90 with a VLAN.
- Create VXLAN 90 on Border-2 and associate VXLAN 90 with a VLAN.
- Create overlay router interfaces for VXLAN 10, VXLAN 20, and VXLAN 30 on TOR-1 and TOR-2 and configure the VXLAN gateway IP address for them. Configure different VRF networks for different overlay router interfaces to

	<p>determine their respective tenants. Configure the anycast gateway to ensure that all VXLAN gateways on the network use the same IP address and MAC address. As the anycast gateway function is enabled, the overlay router interfaces associated with the same VXLAN on TOR-1 and TOR-2 must be configured with the same VXLAN gateway IP address.</p> <ul style="list-style-type: none"> <li>● Create overlay router interfaces for VXLAN 100 and VXLAN 200 on TOR-1 and TOR-2 and configure different VRF networks for the overlay router interfaces. VXLAN 100 and VXLAN 200 serve as the symmetric VXLANs of the corresponding VRF networks.</li> <li>● Create overlay router interfaces for VXLAN 100 and VXLAN 200 on Border-1 and Border-2. Configure different VRF networks for the overlay router interfaces so that VXLAN 100 and VXLAN 200 serve as the symmetric VXLANs of the corresponding VRF networks. Configure VXLAN gateway IP addresses for Border-1 and Border-2 (different IP addresses for different devices).</li> <li>● Create overlay router interfaces for VXLAN 90 on Border-1 and Border-2. Configure different VRF networks for the OverlayRouter interfaces and configure the VXLAN gateway IP address.</li> <li>● Associate VXLAN instances with overlay router interfaces on TOR-1, TOR-2, Border-1, and Border-2 to realize VXLAN routing.</li> <li>● (Optional) Configure ARP suppression on TOR-1 and TOR-2 to reduce the ARP packets entering the VXLAN.</li> </ul>
<b>HOST</b>	Configuring the IP address and gateway according to Figure 2-28 (the detailed configuration on the server is omitted herein).
<b>TOR1</b>	<pre> TOR1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. ### 2.4.3 Configuring an EVPN Distributed Network to Be Compatible with Non-EVPN VTEP Devices

#### Configuration Effect

- Enable the control plane learning function to implement VXLAN tunnel learning, MAC address learning, and route learning via control plane protocols, thereby finally implementing VXLAN bridging, VXLAN routing, and data communication between VXLANs and between a VXLAN and an external network.
- Support functions such as anycast gateways, symmetric VXLAN instances, ARP suppression, and IPv6 ND suppression in EVPN control plane mode.
- Non-EVPN VTEP devices establish tunnels with EVPN-supported VTEP devices to implement the VXLAN bridging and forwarding function.

#### Notes

- VXLAN instances require the support from existing unicast routes on the network. Therefore, an IPv4 unicast routing protocol such as OSPF must be configured on the network devices.
- VXLAN needs the MP-BGP-EVPN protocol to implement VXLAN tunnel learning, MAC address learning, and route learning. Therefore, BGP must be configured on EVPN-supported network devices.

#### Configuration Steps

##### ✚ Configuring a Loopback Interface Associated with the Local End

- Mandatory for devices supporting the EVPN address family.
- Configure the IP address of a loopback interface as the IP address of the local VTEP. One device can be associated with only one loopback interface and the IP address of the loopback interface serves as the VXLAN VTEP IP address.
- If the L3 egress is an overlay router interface during static route configuration, the next-hop IP address cannot be set to the VTEP IP address.

##### ✚ Configuring a Virtual MAC Address for Anycast Gateways

- Optional.
- When anycast gateways are required, a unified virtual MAC address must be configured and used as the MAC address of the anycast gateways. The anycast function can be enabled on the VXLAN overlay router interfaces of the local device only after the virtual MAC address is configured.

##### ✚ Configuring ARP Suppression

- Optional.
- After ARP suppression is enabled, the VTEP device responds to ARP requests from hosts as a proxy, to reduce flooded ARP data on the network.

- ARP suppression is generally enabled on distributed gateways in distributed deployment scenarios.

#### ▾ **Configuring ARP Proxy**

- Optional.
- After ARP suppression is enabled on a VTEP device, you can enable the ARP proxy function on an overlay router interface.
- After ARP proxy is enabled, the VTEP device responds to ARP requests from hosts as a proxy and the MAC address used for proxy response is the gateway MAC address configured on the VTEP device. In this way, the MAC address in the ARP request responses are the MAC address of the VTEP device, and the traffic between hosts in the same VNI is forwarded at L3.
- ARP proxy can be enabled only on VXLAN gateways and is generally enabled on distributed gateways in distributed deployment scenarios.

#### ▾ **Configuring IPv6 ND Suppression**

- Optional.
- After IPv6 ND suppression is enabled, the VTEP device responds to NS multicast packets from hosts as a proxy, to reduce flooded NS multicast packets on the network.
- IPv6 ND suppression is generally enabled on distributed gateways in distributed deployment scenarios.

#### ▾ **Configuring the EVPN Protocol Packet Control Function**

- In symmetric EVPN deployment scenarios, the EVPN protocol packet control function can be configured on TOR switches to reduce the traffic of EVPN packets.

Currently, the EVPN protocol packet control function includes the following:

- Extracting MAC entries from EVPN MAC-IP type-2 routes (ARP entries) on a L2-VPN VXLAN instance
- Extracting MAC entries from EVPN MAC-IPv6 type-2 routes (IPv6 ND entries) on a L2-VNI VXLAN instance
- Banning synchronization of the local MAC address to the remote VTEP through EVPN messages on an L2-VNI VXLAN instance
- Banning delivery of the MAC addresses remotely synchronized through EVPN messages to the local MAC address table on an L2-VNI VXLAN instance
- Stopping an L2-VNI VXLAN instance from generating EVPN type-2 routes

#### ▾ **Creating a VXLAN Instance**

- Mandatory.

#### ▾ **Associating the VXLAN Instance with an Overlay Router Interface**

- Mandatory for VXLAN gateways.
- The device supports the VXLAN routing function and can serve as a VXLAN IP gateway only after the VXLAN is associated with an overlay router interface.

#### ▾ **Associating the VXLAN Instance with a VLAN**

- Mandatory for VXLAN devices directly connected to hosts.
- Packets of a VLAN are encapsulated into VXLAN packets for forwarding only after the VLAN is associated with a VXLAN instance.

- After a VLAN is associated with a VXLAN, all packets of the VLAN will be encapsulated into VXLAN packets. Therefore, an SVI on the device cannot be used as the IP gateway of the VLAN.

#### ↘ **Configuring Overlay Tunnels**

- Mandatory for a VTEP not supporting EVPN and devices that directly communicate with the VTEP.
- The type of tunnels mutually established by two VTEP devices must be the same. The tunnels are those delivered by the SDN controller, statically configured on the CLI, or auto-discovered by EVPN.

#### ↘ **Configuring the Source and Destination IP Addresses for Overlay Tunnels**

- Mandatory for a VTEP not supporting EVPN and devices that directly communicate with the VTEP.

#### ↘ **Associating the VXLAN Instance with the Overlay Tunnels**

- Mandatory for a VTEP not supporting EVPN and devices that directly communicate with the VTEP.
- This command is used to statically specify VXLAN tunnels.

#### ↘ **Configuring Storm Control for the VXLAN Instance**

- Optional.
- This function is required only when the storm rate needs to be limited for a VXLAN instance.

#### ↘ **Configuring the VXLAN UDP Destination Port**

- Optional. The VXLAN UDP destination port used by early devices may not be port 4789. You can run this command to achieve compatibility. In addition, you can also run this command to specify the VXLAN UDP destination port.
- The VXLAN UDP destination port 4789 designated by IANA is used by default.

#### ↘ **Configuring Symmetric Instances**

- Optional.
- Symmetric instances need to be configured only in symmetric scenarios. Only one symmetric instance can be configured in each VRF instance. After a symmetric instance is configured in a VRF instance, L3 forwarding in other asymmetric instances is switched to the symmetric instance.

#### ↘ **Configuring VXLAN Static Routes**

- Optional.
- Configure VXLAN static routes for VXLAN instances if required.

#### ↘ **Configuring the Synchronization of MAC Entries Whose Egresses Are Static Tunnels**

- Optional.
- Configure this function when MAC entries with the egress of static tunnels need to be synchronized externally.

#### ↘ **Configuring the Synchronization of ARP Entries Whose Egresses Are Static Tunnels**

- Optional.
- Configure this function when ARP entries with the egress of static tunnels need to be synchronized externally.

## Verification

The device can establish VXLAN tunnels and obtain VXLAN MAC entries and VXLAN routing entries via EVPN control plane learning. The tunnels and entries can be those delivered by the SDN controller or statically configured on the CLI. They implement the inter-VTEP communication. Run the following commands for verification.

- Run the **show vxlan vni-number** command to check whether the local and remote VXLAN devices learn the peer VTEP neighbor relationships.
- Run the **show vxlan mac** to check whether the VXLAN MAC addresses are learned.
- Run the **show arp** command to check whether the ARP entry of the VXLAN IP gateway is learned.
- Run the **show ipv6 neighbors** command to check whether all local/remote IPv6 ND entries are learned.
- Run the **show vxlan udp-port** command to display the VXLAN UDP destination port.

#### Related Commands

##### ↘ Configuring a Loopback Interface Associated with the Local End

<b>Command</b>	<b>source loopback</b> <i>loopback-port-id</i>
<b>Parameter Description</b>	<i>loopback-port-id</i> : Indicates the ID of the loopback interface.
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	The local VTEP IP address is the IP address of the configured loopback interface.

##### ↘ Configuring a Virtual MAC Address for Anycast Gateways

<b>Command</b>	<b>fabric anycast-gateway-mac</b> <i>mac-addr</i>
<b>Parameter Description</b>	<i>mac-addr</i> : Indicates the MAC address in the format of <i>xxxx.xxxx.xxxx</i> .
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	All gateways on which the anycast function is enabled use this MAC address as the gateway MAC address. The virtual MAC address for anycast gateways cannot be set to the local MAC address or the MAC address of any device on the overlay network.

##### ↘ Configuring Remote ARP Packet Learning

<b>Command</b>	<b>remote arp learn enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the remote ARP packet learning function globally. After this function is enabled, the VXLAN gateways will learn ARP entries from the VXLAN-encapsulated ARP packets received from VXLAN tunnels.

##### ↘ Configuring Remote IPv6 ND Protocol Packet Learning

<b>Command</b>	<b>remote nd learn enable</b>
<b>Parameter</b>	N/A

<b>Description</b>	
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the remote IPv6 ND packet learning function globally. After this function is enabled, the device can learn IPv6 ND entries from the VXLAN-encapsulated IPv6 NS packets received from VXLAN tunnels.

#### ▾ Configuring Global ARP Suppression

<b>Command</b>	<b>arp suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode
<b>Usage Guide</b>	Enable or disable the global ARP suppression function. After ARP suppression is enabled, the switch responds to ARP requests from hosts as a proxy. The VNI-based ARP suppression may be also supported, depending on the product type. You can configure global ARP suppression or VNI-based ARP suppression based on the actual application scenario.

#### ▾ Configuring VNI-based ARP Suppression

<b>Command</b>	<b>arp suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Enable or disable VNI-based ARP suppression. After ARP suppression is enabled, the switch responds to ARP requests from hosts as a proxy. The global ARP suppression may be also supported, depending on the product type. You can configure global ARP suppression or VNI-based ARP suppression based on the actual application scenario.

#### ▾ Configuring ARP Proxy

<b>Command</b>	<b>route-in-vni</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	After the intra-VNI routing function (ARP proxy) is enabled on an overlay router interface, the VTEP device uses its gateway MAC address to respond to all ARP requests from hosts in the VNI, to which the overlay router interface belongs, when serving as an ARP proxy. In this way, the communication traffic between hosts in the same VNI is forwarded through VXLAN routes.

#### ▾ Configuring Global IPv6 ND Suppression

<b>Command</b>	<b>nd suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VTEP configuration mode

<b>Usage Guide</b>	Enable or disable the global IPv6 ND suppression function. After IPv6 ND suppression is enabled, the device responds to IPv6 NS multicast packets from hosts as a proxy. The VNI-based IPv6 ND suppression may be also supported, depending on the product type. You can configure global IPv6 ND suppression or VNI-based IPv6 ND suppression based on the actual application scenario.
--------------------	--

#### ▾ Configuring VNI-based IPv6 ND Suppression

<b>Command</b>	<b>nd suppress enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Enable or disable the VNI-based IPv6 ND suppression function. After IPv6 ND suppression is enabled, the device responds to IPv6 NS multicast packets from hosts as a proxy. The global IPv6 ND suppression may be also supported, depending on the product type. You can configure global IPv6 ND suppression or VNI-based IPv6 ND suppression based on the actual application scenario.

#### ▾ Extracting MAC Entries from EVPN MAC-IP Type-2 Routes (ARP Entries)

<b>Command</b>	<b>evpn arp mac-learning enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device parses one ARP entry and one MAC entry from a MAC-IP type-2 route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is disabled by default and the device parses one ARP entry but no MAC entry from a MAC-IP type-2 route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only the EVPN entry parsing of the VXLAN instance. Other VXLAN instances, for which this command is not configured, are not affected.</p> <p>This command can be used in combination with the <b>evpn mac advertise disable</b> command. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IP type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IP type-2 routes.</p> <p>In symmetric deployment scenarios, this command is configured on L3-VNI VXLAN instances (that is, symmetric instances).</p>

#### ▾ Extracting MAC Entries from EVPN MAC-IPv6 Type-2 Routes (IPv6 ND Entries)

<b>Command</b>	<b>evpn nd mac-learning enable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device parses one IPv6 ND entry and one MAC entry from a MAC-IPv6 type-2 route (IPv6 ND entry) synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is disabled by default and the device parses one IPv6 ND entry but no MAC entry from a MAC-IPv6 type-2</p>

	<p>route synchronized from the VXLAN-EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only the EVPN entry parsing of the VXLAN instance. Other VXLAN instances, for which this command is not configured, are not affected.</p> <p>This command can be used in combination with the <b>evpn mac advertise disable</b> command. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IPv6 type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IPv6 type-2 routes.</p> <p>This command is configured on L2-VNI VXLAN instances.</p>
--	--

#### ↘ Configuring an L2-VNI VXLAN Instance Not to Synchronize the Local MAC Address to the Remote VTEP Through EVPN Messages

<b>Command</b>	<b>evpn mac advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP can learn the MAC entry from the MAC-only type-2 route.</p> <p>After this command is configured, the device does not generate VXLAN-EVPN MAC-only type-2 routes based on MAC entries, and therefore, it will not advertise MAC-only type-2 routes to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates MAC-only type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate MAC-only type-2 routes.</p> <p>This command can be used in combination with the <b>evpn arp mac-learning enable</b> and <b>evpn nd mac-learning enable</b> commands. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IP type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IP or MAC-IPv6 type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

#### ↘ Configuring an L2-VNI VXLAN Instance Not to Deliver MAC Addresses Remotely Synchronized Through EVPN Messages to the Local MAC Address Table

<b>Command</b>	<b>evpn mac inactive</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>After this command is configured, the device does not learn MAC entries from VXLAN-EVPN type-2 routes (MAC-IP or MAC-only type-2 routes) synchronized from neighbors.</p> <p>This command is not configured on a device by default. The device learns MAC entries from VXLAN-EVPN type-2 routes synchronized from neighbors.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance learns MAC entries from VXLAN-EVPN type-2 routes. Other VXLAN instances, for which this command is not configured, can still learn MAC entries.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

### ✎ Configuring an L2-VNI VXLAN Instance Not to Generate EVPN Type-2 Routes

<b>Command</b>	<b>evpn rt-2 advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP learns the MAC entry from the MAC-only type-2 route. In addition, the device generates one MAC-IP type-2 route through the VXLAN-EVPN protocol based on a locally learned ARP entry and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the ARP entry and host route from the MAC-IP type-2 route. The device generates one MAC-IPv6 type-2 route through the VXLAN-EVPN protocol based on a locally learned IPv6 ND entry, and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the IPv6 ND entry and host route from the MAC-IPv6 type-2 route. After this command is configured, the MAC entries, ARP entries, and IPv6 ND entries of the device are not used to generate VXLAN-EVPN type-2 routes and therefore, no type-2 route is advertised to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

### ✎ Creating an Overlay Router Interface

<b>Command</b>	<b>interface OverlayRouter <i>port-id</i></b>
<b>Parameter Description</b>	<i>port-id</i> : Indicates the ID of an overlay router interface.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This interface serves as the VXLAN IP gateway in the VXLAN routing environment. It is similar to an SVI interface in a VLAN.

### ✎ Configuring an IP Address for the Overlay Router Interface

<b>Command</b>	<b>ip address <i>ip-address mask</i></b>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IP address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This IP address serves as the VXLAN IP gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.

### ✎ Configuring an IPv6 Address for the Overlay Router Interface

<b>Command</b>	<b>ipv6 address <i>ip-address mask</i></b>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv6 address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.

<b>Command</b>	Overlay router interface configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	This IPv6 address serves as the VXLAN IPv6 gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.

#### ↘ Associating the Overlay Router Interface with a VRF Instance

<b>Command</b>	<b>vrf forwarding</b> <i>table name</i>
<b>Parameter</b>	<i>table name</i> : Indicates the VRF instance, with which the overlay router interface is associated.
<b>Description</b>	
<b>Command</b>	Interface configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	This command is used to associate with a VRF instance in the VXLAN routing environment and is used for VXLAN L3 routing isolation.

#### ↘ Creating a VXLAN Instance or Entering the VXLAN Configuration Mode

<b>Command</b>	<b>vxlan</b> <i>vni-number</i>
<b>Parameter</b>	<i>vni-number</i> : Indicates the VNI. The value ranges from 1 to 16,777,215.
<b>Description</b>	
<b>Command</b>	Global configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	N/A

#### ↘ Configuring a Symmetric Instance

<b>Command</b>	<b>symmetric</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command</b>	VXLAN configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	No symmetric instance is configured by default. A symmetric instance is used to manage L3 forwarding entries of all asymmetric instances in the VRF instance associated with the symmetric instance.

#### ↘ Associating the VXLAN Instance with the Overlay Router Interface

<b>Command</b>	<b>router-interface</b> <i>interface-name</i>
<b>Parameter</b>	<i>interface-name</i> : Indicates the name of the overlay router interface.
<b>Description</b>	
<b>Command</b>	VXLAN configuration mode
<b>Mode</b>	
<b>Usage Guide</b>	The <b>overlay router interfaces</b> between VXLANs cannot conflict with each other and different VXLANs cannot associate with the same overlay router interface.

#### ↘ Creating an Overlay Tunnel Interface

<b>Command</b>	<b>interface OverlayTunnel</b> <i>port-id</i>
<b>Parameter</b>	<i>port-id</i> : Indicates the ID of an overlay tunnel interface.

<b>Description</b>	
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This interface is used to statically create an overlay tunnel. You can run the <b>tunnel-interface</b> command to associate it with a VXLAN.

#### ↘ Configuring a Tunnel Source IP Address for the Overlay Tunnel Interface

<b>Command</b>	<b>tunnel source</b> <i>ip-address</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the tunnel source IP address.
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	This command is used to specify the source IP address of an overlay tunnel. When packets are encapsulated and forwarded, the outer source IP address of the packets is the source IP address of an overlay tunnel.

#### ↘ Configuring a Tunnel Destination IP Address for the Overlay Tunnel Interface

<b>Command</b>	<b>tunnel destination</b> <i>ip-address</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the tunnel destination IP address.
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	This command is used to specify the destination IP address of an overlay tunnel. When packets are encapsulated and forwarded, the outer destination IP address of the packets is the destination IP address of an overlay tunnel. The tunnel destination IP address is unique globally. Different overlay tunnels cannot share the same destination IP address. Otherwise, a configuration conflict will occur.

#### ↘ Associating the VXLAN Instance with the Overlay Tunnel Interface

<b>Command</b>	<b>tunnel-interface</b> <i>interface-name</i>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the name of an overlay tunnel interface.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	This command is used to statically specify a VXLAN VTEP.

#### ↘ Configuring the VXLAN UDP Destination Port

<b>Command</b>	<b>vxlan udp-port</b> <i>port-number</i>
<b>Parameter Description</b>	<i>port-number</i> : Indicates the UDP destination port ID. The value ranges from 0 to 65535 and the default value is 4789.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	The VXLAN UDP destination port cannot be set to a commonly used UDP port.

#### ↘ Configuring Storm Control for the VXLAN Instance

<b>Command</b>	<b>storm-control {broadcast   multicast   unicast} [kpbs-value   pps pps-value]</b>
<b>Parameter</b>	<i>kpbs-value</i> : Indicates the rate limit value, in kbit/s.
<b>Description</b>	<i>pps-value</i> : Indicates the rate limit value, in packets/second.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	Configure this function when the storm rate needs to be limited based on the VNI.

#### 📌 Configuring the Synchronization of MAC Entries Whose Egresses Are Static Tunnels

<b>Command</b>	<b>evpn mac advertise enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	Configure this function when MAC entries with the egress of static tunnels need to be synchronized externally.

#### 📌 Configuring the Synchronization of ARP Entries Whose Egresses Are Static Tunnels

<b>Command</b>	<b>evpn macip advertise enable</b>
<b>Parameter</b>	N/A
<b>Description</b>	
<b>Command Mode</b>	Overlay tunnel interface configuration mode
<b>Usage Guide</b>	Configure this function when ARP entries with the egress of static tunnels need to be synchronized externally.

#### 📌 Configuration Example

-  Only configuration related to the VXLAN is described below.
-  Only IPv4 configuration is used as an example below and the IPv6 scenario configuration is largely the same as the IPv4 scenario configuration.

Detailed configuration of a full mesh network:

**Scenario**  
**Figure 2- 29**

Note: Blue lines in the figure indicate the VXLAN tunnels that the manually configured VTEP-1 establishes with other VTEPs.

**Configuration Steps**

- Configure an IPv4 unicast routing protocol (such as OSPF) on core switches, TOR switches, and VTEP to ensure that unicast routes are reachable.
- Configure the BGP-EVPN routing protocol on the CORE and TOR switches to ensure that the four switches establish BGP neighbor relationships and support the EVPN protocol family.
- Configure EVI for BGP-EVPN on the core and TOR switches. For details, see the *BGP-EVPN Configuration Guide*.
- Configure VXLANs on the virtual servers and specify the gateway address for the virtual machines. (Omitted)
- Associate the VTEP with the loopback interface on TOR-1 and TOR-2 for the establishment of tunnels.
- Create VXLAN instances on TOR-1, TOR-2, and VTEP-1 and associate the VXLAN instances with VLANs.
- Configure the same anycast gateway MAC address on TOR-1 and TOR-2 so that the VXLAN anycast gateways on the TOR switches use the same virtual MAC address.
- Create overlay router interfaces on TOR-1 and TOR-2 and configure the VXLAN gateway IP address. Configure different VRF instances for the overlay router interfaces and determine their respective tenants.  
Note that the overlay router interface configuration on TOR-1 and TOR-2 must be the same. That is, on all devices, the IP address and mask configured for the overlay router interfaces associated with the same VXLAN instance must be the same and such overlay router interfaces belong to the same tenant (VRF instance).  
In addition, all overlay router interfaces must be configured as anycast gateways.
- Associate VXLAN instances with overlay router interfaces on TOR-1 and TOR-2 to implement VXLAN routing.
- Create VXLAN overlay tunnels on TOR-1, TOR-2, and VTEP-1 and configure the SIP and DIP.
- (Optional) Configure ARP suppression on TOR-1 and TOR-2 to reduce ARP packets flowing into the VXLAN.

**HOST**

The detailed configuration of the servers is omitted here. Configure the IP address and gateway according to the figure above.

**CORE**

VXLAN does not need to be configured on the core switches. The OSPF and BGP network configurations are omitted here.

**TOR-1**

#### 2.4.4 Configuring L2 Subinterfaces to Access a VXLAN

##### Configuration Effect

- Configure hosts to access a VXLAN through L2 subinterfaces.
- L2 subinterfaces can access a VXLAN in VLAN encapsulation or untagged encapsulation mode.

##### Notes

- If the main interface is a trunk interface, the subinterfaces are not recommended to access a VXLAN in untagged encapsulation mode due to chip limitations. If the untagged encapsulation mode is configured for the subinterfaces, tagged packets are transferred to the logic of subinterfaces using the untagged packaging mode.
- The extend-VLAN configured for a VXLAN instance is like the VLAN or untagged encapsulation rule configured for a subinterface. When a subinterface is available, the encapsulation rule of the subinterface has a higher priority than the extend-VLAN configured for a VXLAN instance.

##### Configuration Steps

###### ▾ Configuring the VXLAN Encapsulation Rule for a Subinterface

- Mandatory.
- Configure the VXLAN encapsulation rule for a specified subinterface.

###### ▾ Configuring the VLAN and Untagged Encapsulation Rules for a Subinterface

- Mandatory.
- L2 subinterfaces can access a VXLAN in VLAN encapsulation or untagged encapsulation mode.

###### ▾ Creating a VXLAN Instance

- Mandatory.

###### ▾ Associating the VXLAN Instance with an Overlay Router Interface

- Mandatory for VXLAN gateways.
- The device supports the VXLAN routing function and can serve as a VXLAN IP gateway only after the VXLAN is associated with an overlay router interface.

##### Verification

L2 subinterfaces can access the VXLAN. Run the following commands for verification.

- Run the **show vxlan vni-number** command to check the local configuration of the VXLAN.
- Run the **show vxlan mac** to check whether the VXLAN MAC addresses are learned.
- Run the **show arp** command to check whether the ARP entry of the VXLAN IP gateway is learned.
- Run the **show ipv6 neighbors** command to check whether all local/remote IPv6 ND entries are learned.
- Run the **show running** command to display the subinterface configuration.

#### Related Commands

##### ↘ Configuring the VXLAN Encapsulation Rule for a Subinterface

<b>Command</b>	<b>encapsulation vxlan vni-number</b>
<b>Parameter Description</b>	<i>vni-number</i> : Indicates the VNI. The value ranges from 1 to 16,777,215.
<b>Command Mode</b>	L2 subinterface configuration mode
<b>Usage Guide</b>	<ol style="list-style-type: none"> <li>1. Only one VXLAN encapsulation rule can be configured for one subinterface.</li> <li>2. You can preconfigure VXLAN encapsulation rules when no VXLAN instance exists.</li> </ol>

##### ↘ Configuring the VLAN and Untagged Encapsulation Rules for a Subinterface

<b>Command</b>	<b>encapsulation dot1q {untag   s-vid vlan-id}</b>
<b>Parameter Description</b>	<b>{untag   s-vid vlan-id}</b> : Specifies VLAN encapsulation or untagged encapsulation for a port. The VLAN ID ranges from 1 to 4094 when VLAN encapsulation is adopted.
<b>Command Mode</b>	L2 subinterface configuration mode
<b>Usage Guide</b>	If the main interface is a trunk interface, the subinterfaces are not recommended to access a VXLAN in untagged encapsulation mode due to chip limitations. If the untagged encapsulation mode is configured for the subinterfaces, tagged packets are transferred to the logic of subinterfaces using the untagged packaging mode.

##### ↘ Creating an Overlay Router Interface

<b>Command</b>	<b>interface OverlayRouter port-id</b>
<b>Parameter Description</b>	<i>port-id</i> : Indicates the ID of an overlay router interface.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	This interface serves as the VXLAN IP gateway in the VXLAN routing environment. It is similar to an SVI interface in a VLAN.

##### ↘ Configuring an IP Address for the Overlay Router Interface

<b>Command</b>	<b>ip address ip-address mask</b>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IP address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Interface configuration mode

<b>Usage Guide</b>	This IP address serves as the VXLAN IP gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.
--------------------	---

#### ↘ Configuring an IPv6 Address for the Overlay Router Interface

<b>Command</b>	<b>ipv6 address</b> <i>ip-address mask</i>
<b>Parameter Description</b>	<i>ip-address</i> : Indicates the IPv6 address of the overlay router interface. <i>mask</i> : Indicates the subnet mask.
<b>Command Mode</b>	Overlay router interface configuration mode
<b>Usage Guide</b>	This IPv6 address serves as the VXLAN IPv6 gateway address in the VXLAN routing environment. It is similar to the IP address of an SVI in a VLAN.

#### ↘ Associating the Overlay Router Interface with a VRF Instance

<b>Command</b>	<b>vrf forwarding</b> <i>table name</i>
<b>Parameter Description</b>	<i>table name</i> : Indicates the VRF instance, with which the overlay router interface is associated.
<b>Command Mode</b>	Interface configuration mode
<b>Usage Guide</b>	This command is used to associate with a VRF instance in the VXLAN routing environment and is used for VXLAN L3 routing isolation.

#### ↘ Creating a VXLAN Instance or Entering the VXLAN Configuration Mode

<b>Command</b>	<b>vxlan</b> <i>vni-number</i>
<b>Parameter Description</b>	<i>vni-number</i> : Indicates the VNI. The value ranges from 1 to 16,777,215.
<b>Command Mode</b>	Global configuration mode
<b>Usage Guide</b>	N/A

#### ↘ Associating the VXLAN Instance with the Overlay Router Interface

<b>Command</b>	<b>router-interface</b> <i>interface-name</i>
<b>Parameter Description</b>	<i>interface-name</i> : Indicates the name of the overlay router interface.
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	The <b>overlay router interfaces</b> between VXLANs cannot conflict with each other and different VXLANs cannot associate with the same overlay router interface.

#### Configuration Example

-  Only configuration related to the VXLAN is described below.
-  Only IPv4 configuration is used as an example below and the IPv6 scenario configuration is largely the same as the IPv4 scenario configuration.

The recommended configuration is as follows:

<p><b>Scenario</b> <b>Figure 2- 30</b></p>	<p style="text-align: center;"><b>TOR</b></p> <p><b>SERVER</b> VM1: vlan 10 vxlan 10 VM2: vlan 20 vxlan 20</p> <p><b>HOST</b> Physical machine: untag vxlan 10</p>
<p><b>Configuration Steps</b></p>	<ul style="list-style-type: none"> <li>● Configure a virtual server, virtual machine, and physical server (omitted).</li> <li>● Create an L2 subinterface on the TOR switch, configure VXLAN encapsulation and VLAN or untagged encapsulation rule for the subinterface.</li> <li>● Create an overlay router interface on the TOR switch and configure the VXLAN gateway IP address.</li> <li>● Configure the VXLAN instance to associate with the overlay router interface on the TOR switch to implement VXLAN routing.</li> </ul>
<p><b>TOR</b></p>	<pre>TOR# configure terminal TOR(config)#vlan 10 TOR(config-vlan)#exit TOR(config)#vlan 20 TOR(config-vlan)#exit TOR(config)#interface TFGigabitEthernet 0/1 TOR(config-if-TFGigabitEthernet 0/1)#switchport mode trunk TOR(config-if-TFGigabitEthernet 0/1)#exit TOR(config)#interface TFGigabitEthernet 0/1.1 TOR(config-subif-TFGigabitEthernet 0/1.1)#encapsulation dot1q s-vid 10 TOR(config-subif-TFGigabitEthernet 0/1.1)#encapsulation vxlan 10 TOR(config-subif-TFGigabitEthernet 0/1.1)#exit TOR(config)#interface TFGigabitEthernet 0/1.2 TOR(config-subif-TFGigabitEthernet 0/1.2)#encapsulation dot1q s-vid 20 TOR(config-subif-TFGigabitEthernet 0/1.2)#encapsulation vxlan 20 TOR(config-subif-TFGigabitEthernet 0/1.2)#exit TOR(config)#interface TFGigabitEthernet 0/2 TOR(config-if-TFGigabitEthernet 0/2)#switchport mode access vlan 10 TOR(config-if-TFGigabitEthernet 0/2)#exit TOR(config)#interface TFGigabitEthernet 0/2.1 TOR(config-subif-TFGigabitEthernet 0/2.1)#encapsulation dot1q untag TOR(config-subif-TFGigabitEthernet 0/2.1)#encapsulation vxlan 10</pre>

- Banning synchronization of the local MAC address to the remote VTEP through EVPN messages on an L2-VNI VXLAN instance
- Banning delivery of the MAC addresses remotely synchronized through EVPN messages to the local MAC address table on an L2-VNI VXLAN instance
- Stopping an L2-VNI VXLAN instance from generating EVPN type-2 routes

📌 **Configuring an L2-VNI VXLAN Instance Not to Synchronize the Local MAC Address to the Remote VTEP Through EVPN Messages**

<b>Command</b>	<b>evpn mac advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP can learn the MAC entry from the MAC-only type-2 route.</p> <p>After this command is configured, the device does not generate VXLAN-EVPN MAC-only type-2 routes based on MAC entries, and therefore, it will not advertise MAC-only type-2 routes to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates MAC-only type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate MAC-only type-2 routes.</p> <p>This command can be used in combination with the <b>evpn arp mac-learning enable</b> and <b>evpn nd mac-learning enable</b> commands. After they are executed, the network-wide VXLAN-EVPN neighbors synchronize only MAC-IP type-2 routes but no MAC-only type-2 routes. All devices parse and extract MAC entries from MAC-IP or MAC-IPv6 type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

📌 **Configuring an L2-VNI VXLAN Instance Not to Deliver MAC Addresses Remotely Synchronized Through EVPN Messages to the Local MAC Address Table**

<b>Command</b>	<b>evpn mac inactive</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	After this command is configured, the device does not learn MAC entries from VXLAN-EVPN type-2 routes (MAC-IP or

	<p>MAC-only type-2 routes) synchronized from neighbors.</p> <p>This command is not configured on a device by default. The device learns MAC entries from VXLAN-EVPN type-2 routes synchronized from neighbors.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance learns MAC entries from VXLAN-EVPN type-2 routes. Other VXLAN instances, for which this command is not configured, can still learn MAC entries.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

### 📌 Configuring an L2-VNI VXLAN Instance Not to Generate EVPN Type-2 Routes

<b>Command</b>	<b>evpn rt-2 advertise disable</b>
<b>Parameter Description</b>	N/A
<b>Command Mode</b>	VXLAN configuration mode
<b>Usage Guide</b>	<p>This command is not configured on a device by default. The device generates one MAC-only type-2 route through the VXLAN-EVPN protocol based on a locally learned MAC entry, and synchronizes the type-2 route to the EVPN neighbor (that is, remote VTEP). Then, the remote VTEP learns the MAC entry from the MAC-only type-2 route. In addition, the device generates one MAC-IP type-2 route through the VXLAN-EVPN protocol based on a locally learned ARP entry and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the ARP entry and host route from the MAC-IP type-2 route. The device generates one MAC-IPv6 type-2 route through the VXLAN-EVPN protocol based on a locally learned IPv6 ND entry, and synchronizes the type-2 route to the EVPN neighbor. Then, the remote VTEP learns the IPv6 ND entry and host route from the MAC-IPv6 type-2 route. After this command is configured, the MAC entries, ARP entries, and IPv6 ND entries of the device are not used to generate VXLAN-EVPN type-2 routes and therefore, no type-2 route is advertised to the EVPN neighbor.</p> <p>This command is configured on a VXLAN instance and affects only whether the VXLAN instance generates type-2 routes. Other VXLAN instances, for which this command is not configured, can still generate type-2 routes.</p> <p>Note: This command can be configured only on L2-VNI VXLAN instances (that is, VXLAN instances with the <b>symmetric</b> command not configured). It is unavailable on L3-VNI VXLAN instances.</p>

## 2.5 Monitoring

### Displaying

Description	Command
Displays the VXLAN configuration and status of the device.	<b>show vxlan vni-number</b>
Displays the MAC addresses learned by the device.	<b>show vxlan mac [vni vni-number] [address mac-address]</b>
Displays the VXLAN ARP entries learned by the device.	<b>show arp</b>
Displays the VXLAN IPv6 ND entries learned by the device.	<b>show ipv6 neighbors</b>
Displays the global configurations of the device, such as the VTEP IP address and anycast MAC address.	<b>show vxlan global</b>
Displays the ARP suppression status of the device.	<b>show vxlan arp suppress</b>
Displays the VXLAN UDP destination port of the device.	<b>show vxlan udp-port</b>
